JULY, 1935, to DECEMBER, 1935

"To the solid ground
Of nature trusts the Mind that builds for aye."—WORDSWORTH.

London
MACMILLAN AND CO., LIMITED
NEW YORK: THE MACMILLAN COMPANY

INDEX

NAME INDEX

Abel (Prof. O.), Vorzeitliche Lebensspuren (*Review*), 492
Abell (Prof. T. B.), appointed pro-vice-chancellor of Liverpool University, 117
Abbot (Dr. C. G.), Solar Radiation andWeather Studies, 959
Achard (C.), and A. Boutaric, Changes undergone by the Blood Serum under the Influence of Heat, 42; and A. Boutaric and J. Bouchard, Comparative Action of Ordinary Alkaloids and Genalkaloids on the Fluorescence of Uranine Solutions, 806; and M. Piettre, Proteins of the Cancer Cell, 883
Acharya (Dr. C. N.), Structure and Oxidation of Nitrogenous Substances, 644
Acton (Lieut.-Col. H. W.), [death], 328
Adair (Dr. M. E.), elected John Lucas Walker student in Cambridge University, 524
Adam (Dr. N. K.), Surface Chemistry, 499
Adam (W. B.), Production of Vegetables for Canning, 725
Adams (H. P.), The Life and Writings of Giambattista Vico (*Review*), 1010
Adamczewski (I.), [Prof. C. Białobrzeski and], Cosmic Ray Bursts in Liquid Dielectries, 109; Application of Dielectric Liquids to the Study of the 'Bursts' of Ionisation caused by the Cosmic Rays, 157
Adams (Dr. C. E.), and Dr. J. Henderson, Seismology in New Zealand, 763
Adams (Dr. E. W.), Agranulocytic Angina, 72
Adams (S.), [H. C. Weston and], Conditions of Noise, 799
Adamson (R. S.), Stem Structure of *Boscia rehmanniana*, Pest., 312
Adrian (Prof. E. D.), appointed a trustee of the Beit memorial fellowships for medical research, 100
Agamennone (Prof. G.), History of the Italian Seismological Society, 256
Ahmad (B.), Estimation of Ascorbic Acid by Titration, 797
Ainsworth (Dr. G. C.), Dr. G. H. Berkeley and Dr. J. Caldwell, English and Canadian Tomato Virus Diseases, 400
Aitken (Dr. R. G.), The Binary Stars. Second edition (*Review*), 590
Alderson (J.), The Case for Vivisection, 63
Aldis (R. W.), [D. Norris, P. M. Glover and], Lac and the Indian Lac Research Institute, 545
Alexander (R. C.), appointed professor of surgery in St. Andrews University, 881
Alfvén (Dr. H.), Registration of the Ionisation Curve of a Single α-Particle, 70; 394
Alicata (J. E.), [B. Schwartz and], Life-History of *Longistriata musculi*, 150
Alichanian (A. I.), [Prof. A. I. Alichanow, B. S. Dželepow and], Beta Ray Spectra of Artificially Produced Radioactive Elements, 257; [Prof. A. I. Alichanow, M. S. Kosodaew and], Emission of Positrons from a Thorium-Active Deposit, 475; Emission of Positrons from Radioactive Sources, 719
Alichanow (Prof. A. I.), A. I. Alichanian and B. S. Dželepow, Beta Ray Spectra of Artificially Produced Radioactive Elements, 257; and A. I. Alichanian and M. S. Kosodaew, Emission of Positrons from a Thorium-Active Deposit, 475; Emission of Positrons from Radioactive Sources, 719
Allen (Dr. C. W.), Intensities of Fraunhofer Lines, 920
Allen (Prof. G. C.), British Industries and their Organisation. Second edition (*Review*), 322
Allen (R.), [Dr. G. Bourne and], Vitamin C in Lower Organisms, 185
Allen (Dr. W. M.), Prof. A. Butenandt, Prof. G. W. Corner and K. H. Slotta, Nomenclature of Corpus Luteum Hormone, 303
Allison (Prof. S. K.), [Prof. A. H. Compton and], X-Rays in Theory and Experiment. Second edition of "X-Rays and Electrons", by Prof. A. H. Compton (*Review*), 661
Allsop (G.), and H. Lloyd, A Recording Manometer having Low Inertia, 151
Almquist (H. J.), and E. L. R. Stopstad, Dietary Hæmorrhagic Disease in Chicks, 31
Alquier (R.), [A. Cornillot and], Reaction of Acetylene with Acetyl Chloride, 925
Ames (W. M.), The Chemist and the Community, 83
Ampthill (Lord), bequest to the Victoria and Albert Museum, 946
Ananthakrishnan (R.), Raman Spectrum of Heavy Water, 551
Andant (A.), P. Lambert and J. Lecomte, Diffusion Spectra (Raman Effect) and Infra-Red Absorption Spectra of Saturated Fatty Alcohols and Ethylene Hydro-carbons, 525
Anderson (Prof. D. F.), awarded a Rockefeller travelling fellowship, 64
Anderson (Dr. E.), and Dr. W. B. Turrill, Biometrical Studies on Herbarium Material, 986
Anderson (Capt. E. A.), [Capt. A. W. Stevens and], Record Ascent in the American Stratosphere Balloon, *Explorer II*, 786
Anderson (W. A.), and W. Kerns, Interests, Activities and Problems of Rural Young Folk (2), 838
Andrade (Prof. E. N. da C.), Robert Hooke and his Contemporaries, 358; 603; Plasticity of Bismuth, 915
Angenot (P.), [V. Henri and], Relation between the Ultra-Violet Absorption Spectrum and the Raman Spectrum of Pyridine, 964
Angus (Dr. W. R.), and others, Infra-Red Spectrum of Hexadeuterobenzene and the Structure of Benzene, 680
Anschütz (Prof. R.), elected a foreign honorary fellow of the Royal Society of Edinburgh, 27
Antoniadi (E. M.), Recent Observations of the Planet Mars, 311
Antoniani (C.), β-Glucosidase of *Sorghum*, 306
Appleton (Prof. E. V.), Temperature Changes in the Higher Atmosphere, 52; Scientific Progress (Sir Halley Stewart Trust lecture), 711; and Miss L. J. Ingram, Magnetic Storms and the Upper-Atmospheric Ionisation, 548; and R. Naismith, Ionisation of the Upper Atmosphere, 557
Arber (Dr. Agnes), The Gramineae: a Study of Cereal, Bamboo and Grass (*Review*), 317
Archer (W.), edited by T. Besterman, On Dreams (*Review*), 597

Arditti (G.), Autoxidation of Normal Hexadecane, 525
Armitage (Miss E.), Early Frost in 1835 and 1935, 753
Armstrong (A. L.), Flint-mining at Grime's Graves, Norfolk, 687
Armstrong (Dr. E. F.), Past and Future of Chemical Industry (Medallist's address to the Society of Chemical Industry), 212; elected president of the Association of British Chemical Manufacturers, 640
Armstrong (Prof. H. E.), Food, Farmer and Future, 565; School Dietaries, 749
Ashida (Dr. J.), Leaf Blade of *Aldrovanda vesiculosa*, L., 519
Ashworth (Prof. J. H.), Charles Darwin as a student in Edinburgh, 1825-27, 1011
Astbury (W. T.), Dr. R. D. Preston and Dr. A. G. Norman, X-Ray Examination of the Effect of Removing Non-Cellulosic Constituents from Vegetable Fibres, 391; and W. A. Sisson, Structure of Keratin, 557
Aston (Dr. F. W.), Atomic Weight of Terbium, 112; Story of Isotopes, 380; elected president of the Cambridge Philosophical Society, 791
Asundi (Dr. R. K.), M. Jan-Khan and Prof. R. Samuel, Spectra of SeO and SeO_2, 642
Atkinson (F. S.), appointed professor of mining in Leeds University, 730
Auden (J. B.), and A. M. N. Ghosh, Bihar Earthquake of 1934, 485
Avery (A. G.), [J. T. Buchholz, A. F. Blakeslee and], Pollen-Tube Growth of a Translocation of the 1.2 Chromosome in *Datura*, 120
Awbery (J. H.), and Dr. E. Griffiths, Refrigeration Hygrometry, 229
Ayyangar (G. N. R.), and P. V. Hariharan, Observations on *Sorghum*, 73; and V. P. Rao, *Sorghum*, 73

Baccino (M.), Thermal Adaptation of the Nests of Mammals during the Growth of the Young, 449
Badami (Dr. J. S.), Hyperfine Structure and the Gross Structure Analysis of the Spectrum of Doubly Ionised Antimony, 836
Bacharach (A. L.), and H. E. Glynn, Quantitative Determination of Ascorbic Acid, 757
Bache (C.), Excavations at Tepe Gawra, Iraq, 149
Bačkovský (M.), and Prof. V. Dolejšek, Occurrence of the Reversed Absorption Edges of the Long Wave-lengths of X-Rays, 836; the *L*-Emission Spectrum of Argon, 643
Bacon (R. G. R.), awarded a University of London post-graduate travelling studentship, 79
Bacq (Dr. Z. M.), Occurrence of Unstable Choline Esters in Invertebrates, 30
Baggott (E. A.), [Prof. H. Levy and], Numerical Studies in Differential Equations. Vol. I (*Review*), 458
Bailey (C. H.), The Engineer and the Community, 902
Bailey (C. R.), and others, Infra-Red Spectrum of Hexadeuterobenzene and the Structure of Benzene, 680
Bailey (Dr. W. N.), Generalized Hypergeometric Series (*Review*), 595
Baird (H. F.), Surface Structure beneath the Pacific, 723
Baker (Dr. J. R.), Stereoscopic Photography, 193; 551
Baker (R. St. Barbe), Contribution of Trees to National Health and Efficiency (Chadwick lecture), 713
Baldet (F.), Resolution of Nova Herculis, 1934, 487
Balfour (H.), granted the title of professor by Oxford University, 805; the Pitt-Rivers Museum, Oxford and, 861
Balfour-Browne (Prof. F.), The Species Problem, 382
Baly (Prof. E. C. C.), Kinetics of Heterogeneous Catalysis and of Enzyme Action, 146; The Draft Poisons List and Poison Rules, 248; Kinetics of Photosynthesis, 344; and W. P. Pepper, Adsorption of Aluminium Hydroxide by Kieselguhr, 28
Bancelin (J.), and Y. Crimail, Substances Inhibiting the Corrosion of Iron by Acids, 1038
Banerjee (S. S.), [Prof. S. K. Mitra and], Dielectric Constant of Ionised Air, 512
Banister (Dr. H.), Psychology and Health (*Review*), 319
Barber (C. T.), Natural Gas Resources of Burma, 611
Barbier (D.), D. Chalonge and E. Vassy, Measurement of the Reduced Thickness of Atmospheric Ozone during the Polar Winter, 883
Barbour (Prof. G. B.), Chinese Loess Deposits, 150
Barbour (T.), Reptiles and Amphibia of the Antilles, 228
Barcroft (Sir J.), Velocities of some Physiological Processes, 572
Barger (Prof. G.), F. Bergel and A. R. Todd, A Crystalline Fluorescent Dehydrogenation Product from Vitamin B_1, 259
Barlow (Mrs. Nora), Charles Darwin and the Galapagos Islands, 391
Barnard (G. P.), The Rectifier Photocell, 74
Barnes (Dr. B.), Variation in *Thamnidium elegans*, Link, induced by the Action of High Temperatures, 481
Barnes (H. D.), Lecithin as a Dispersing Agent for Dibenzanthracene, 756
Barnes (R. B.), R. R. Brattain and F. Seitz, Infra-Red Absorption of Crystals, 994
Barnes (R. J.), [R. A. Stephen and], New Technique for obtaining X-Ray Powder Patterns, 793
Barnóthy (Dr. J.), and Dr. M. Forró, Diurnal Variation of Cosmic Ray Intensity and Nova Herculis, 680
Barrett (N. R.), awarded a Rockefeller travelling fellowship, 64
Barrett (W.), The Meaning of Probability, 604
Barrington (E. J. W.), Proteolytic Digestion in the Ammoccete Larva, 145
Bartels (M.), [P. Bartels, Dr. H. H. Ploss and], edited by Dr. E. J. Dingwall, Woman: an Historical, Gynaecological and Anthropological Compendium. 3 Vols. (*Review*), 811
Bartels (P.), [Dr. H. H. Ploss, M. Bartels and], edited by Dr. E. J. Dingwall, Woman: an Historical, Gynaecological and Anthropological Compendium. 3 Vols. (*Review*), 811
Barton (Prof. S. G.), and Prof. W. H. Barton, Jr., A Guide to the Constellations. Second edition (*Review*), 89
Barton, Jr. (Prof. W. H.), [Prof. S. G. Barton and], A Guide to the Constellations (*Review*), 89
Barus (Prof. C.), [death], 672
Bassière (M.), Crystalline Structure of Silver Nitride, 844
Bastings (L.), and R. C. Hayes, Distribution of Earthquakes in New Zealand, 519
Bateman (E. H.), Open Frame Girder, 866
Bauer (E.), and M. Magat, Raman Spectrum of Liquid Heavy Water, 807
Baumgartner (Dr. Leona), Edwin Klebs, 675
Bayliss (N. S.), Absorption Spectrum of Methyl Iodide, 264
Beatty (Dr. R. T.), Radio Data Charts. Second edition, 983
Bechtold (F.), translated by H. E. G. Tyndale, Nanga Parbat Adventure: a Himalayan Expedition (*Review*), 1005
Beck (Prof. G.), Beta Processes and Nuclear Stability, 257
Beck (H. L.), Glazed Stones, 440
Béclère (Dr. A.), elected an honorary member of the German Röntgen Society, 473
Bedon (E.), [A. Guillerd and], Experiment with Fluorescein on the Losses of the Ognon, above Lure (Haute-Saone), 406
Beebe (Dr. W.), Half Mile Down (*Review*), 586
Beeck (O.), Effect of Adsorbed Water on the Catalytic Decomposition of Hydrocarbons (by a Molecular Beam Method), 1028
Beer (Dr. A.), Nova Herculis, 112
de Beer (Dr. G. R.), An Introduction to Experimental Embryology. Second edition (*Review*), 702; the Schools and Pre-Medical Studies, 874
Běhounek (Prof. F.), V. Santholzer and Prof. F. Ulrich, Radioactivity of Oil-Waters in Czechoslovakia, 910
Bělehrádek (Prof. J.), Temperature and Living Matter (*Review*), 412
Belgians (King of the), elected an honorary member of the Linnean Society of London, 786
Bell (Dr. D. J.), Fish and Rabbit Liver Glycogens, 184
Bell (Prof. E. T.), The Search for Truth (*Review*), 493
Bell (F. L. S.), Divination in Melanesia, 72
Bellaschi (P. L.), Lightning Stroke Currents, 961

Bellhouse (Sir Gerald), The Draft Poisons List and Poison Rules, 248
Belling (T.), [P. Jacquinot and], Measurements of the Paschen-Back effect with the Bellevue Electromagnet fitted with Supplementary Coils, 883
Belling (Tsaï), [H. Bizette and], Magnetic Double Refraction of Nitric Oxide, 1001
Beltran (E.), [A. A. Guntz and], Influence of H + ions in the Phenomena of Reduction and Hydrogenation, 157
Benedict (F. G.), and E. G. Ritzman, Lability of the Basal Metabolism of the Dairy Cow, 407
Benedict (Dr. Ruth), Patterns of Culture (*Review*), 325
Benedikt (Prof. M.), centenary of the birth of, work of,
Benjamin (M.), The Oxide-coated Cathode, 306
Bennett (J. S.), appointed assistant lecturer in metallurgy (founding) in Sheffield University, 79
Benson (I.), Psychology of Attention, 610
Benson (R. B.), New Family of Sawflies and the Genera of the Cephidæ, 992
Berg (Dr. W. F.), and L. Sandler, Plasticity of Bismuth, 915
Bergel (F.), [Prof. G. Barger, A. R. Todd and], A Crystalline Fluorescent Dehydrogenation product from Vitamin B_1, 259
Bergmann (L.), [C. Schaefer and], A New Optical Method for the Determination of the Elastic Constants of Crystals, 731
Berkeley (E.), Swarming of *Odontosyllis phosphorea*, Moore, and of other Polychæta near Nanaimo, B.C., 1029
Berkeley (Dr. G. H.), [Dr. G. C. Ainsworth, Dr. J. Caldwell and], English and Canadian Tomato Virus Diseases, 400
Berkey (Prof. C. P.), elected a foreign member of the Geological Society of London; work of, 863
Berliner (Dr. A.), removal from editorship of *Die Naturwissenschaften*; work of, 506
Berman (L.), Spectrum of a Hot Carbon Star, 401
Bernal (J. D.), Study of X-Rays, 661
Bernard (late Prof. L.), proposed memorial to, 27
Bernard (P.), Measurement of the Pressures Developed by Explosive Substances, 43
Bernard (R.), Production of the Vegard-Kaplan bands by the Electronic Bombardment of a Mixture of Argon and Nitrogen, 196
Bernays (P.), [D. Hilbert und], Grundlagen der Mathematik. Band 1 (*Review*), 126
Bertrand (G.), Contributions by the Atmosphere of Sulphur to Arable Soils, 487
Best (A. C.), Transfer of Heat and Momentum in the Lowest Layers of the Atmosphere, 919
Besterman (T.), A. Bibliography of Sir Oliver Lodge, F.R.S. (*Review*), 357
Beuttell (A. W.), Illuminating Engineering, 714
Bhuyan (H. C.), Effect of Light on Diamagnetic Susceptibilities, 872
Białobrzeski (Prof. C.), and I. Adamczewski, Cosmic Ray Bursts in Liquid Dielectrics, 109; Application of Dielectric Liquids to the study of the 'bursts' of Ionisation caused by the Cosmic Rays, 157
Biesheuvel (S.), Nature of Temperament, 312
Biffen (Sir Rowland), conferment upon, of an honorary doctorate by Reading University, 923
Billy (M.), and P. Brasseur, Preparation of Anhydrous Titanium Trichloride, 43
Binder (O.), Decomposition of Pentahydrated Copper Sulphate by Heat, 1038
Biot (M. A.), Quadratic Wave Equation: Flood Waves in a Channel with Quadratic Friction, 488
Birch (T. T. C.), A Phomopsis Disease of Conifers in New Zealand, 189
Bircumshaw (L. L.), [G. D. Preston and], Oxidation of Metals, 764
Bishop (C. W.), Archæological Investigations in Shansi, China, 508
Bizette (H.), [Tsaï Belling and], Magnetic Double Refraction of Nitric Oxide, 1001
Bjerge (T.), and C. H. Westcott, Interaction of Neutrons with Matter, 557
Bjerkan (P.), [T. Gaarder and], Oyster Culture in Norway, 228
Bjerknes (Prof. J.), Mathematical Methods in Meteorology (*Review*), 240
Blaauw (A. H.), [Miss A. M. Hartsema and], Shifting of Periodicity by Means of High Temperatures, 617
Blackett (Prof. P. M. S.), appointed Halley lecturer Oxford University for 1936, 79
Blackman (G. E.), Pasture Research in England, 403
Blair (A.), Social Science Investigation, 607
Blair (Prof. D. MacCallum), appointed regius professor anatomy in Glasgow University, 405
Blair (G. W. S.), [Dr. R. K. Schofield and], Influence of Viscosity Variation on the Rupture of Plastic Bodies, 147
Blair (P. H.), appointed an assistant lecturer in archæology and anthropology in Cambridge University, 768
Blakeslee (A. F.), [J. T. Buchholz, A. G. Avery and], Pollen-Tube Growth of a Translocation of the 1.2 Chromosome in *Datura*, 120
Blatter and McCann, Bombay Grasses, 919
Blau (Marietta), and Hertha Wambacher, Sensitiveness of Desentisised Photographic Films in Dependence on Atmospheric Oxygen and on the Concentration of the Desensitiser, 407
Bleeker (Dr. W.), Photographs of Bright Meteor Trail on March 24, 1935, 224
Bloch (Dr. A.), New Methods for Measuring Mechanical Stresses at Higher Frequencies, 223
Bloch (E.), [L. Bloch, Choong Shin-Piaw and], Emission Spectrum of the Selenium Oxide, SeO, 924
Bloch (Dr. F.), and Dr. C. Møller, Recoil by β-Decay, 911; Production of Neutrons by Annihilation of Protons and Electrons according to Fermi's Theory, 987
Bloch (L.), E. Bloch and Choong Shin-Piaw, Emission Spectrum of the Selenium Oxide, SeO, 924
Blumenthal (H.), Sense-Organs of Spiders, 763
Boas (F.), Tempo of Growth of Fraternities, 487
Bode (F. D.), [C. Stock and], Occurrence of Lower Miocene Mammal-bearing Beds near Death Valley, California, 925
Boeke (Dr. J.), Nerve Plexuses in *Amphioxus*, 305
de Boer (Dr. J. H.), translated from the manuscript of Mrs. H. E. Teves-Acly, Electron Emission and Adsorption Phenomena (*Review*), 589
Bohr (Prof. N.), Quantum Mechanics and Physical Reality, 65; gift to, for the purchase of radium for research, 602
Bois (C.), Destructive Earthquakes in 1934, 472; Destructive Earthquakes in 1935, 639
Bois (Prof. D.), Les plantes alimentaires chez tous les peuples et à travers les âges: Histoire, utilisation, culture, Vol. 3 (*Review*), 663
Bollen (W. B.), [C. H. McBurney, R. J. Williams and], Pantothenic Acid and the Nodule Bacteria—Legume Symbiosis, 407
Bolliger (A.), Volumetric Microdetermination of Magnesium with Methylene Blue following its Precipitation as Magnesium Picrolonate, 449
Bolton (D. J.), P. C. Honey and N. S. Richardson, Electrical Water Heating: with Special Reference to the Domestic Storage Heater (*Review*), 625

TITLE INDEX

α-Particle: Single, Registration of the Ionisation Curve of a, Dr. H. Alfvén, 70; and an Atomic Nucleus, the Field between an, L. Schames, 273; Registration of the Ionisation Curve of a Single, Prof. G. Stetter; Dr. H. Alfvén, 394

α-Rays, Unknown Natural, Question of Existence of, J. Schintlmeister, 450

Aberdeen University: Prof. E. W. H. Cruickshank appointed regius professor of physiology, 562; Dr. W. Hamilton Fyfe appointed principal, 692; Dr. E. M. Wright appointed professor of mathematics, 711

Ability: Opportunity and Social Status, W. F. Floyd, 484; and Educational Opportunity in relation to Parental Occupation, J. L. Gray and Pearl Moshinsky, 484

Absolute Units and Electrical Measurements, Sir Richard Glazebrook, 667

Academic: Assistance Council, Second Annual Report of the, 135; Freedom, 329

Accidents in Well-Lighted Streets, Fewer, 578

Acetylcholine and Sterols in Tissues, Interaction between, Dr. G. S. Carter and Dr. L. W. Mapson, 143

Acetylene: Half-heavy, Structure of, A. Dadieu and O. Kernauner, 450; Reaction of, with Acetyl Chloride, A. Cornillot and R. Alquier, 925

Acids, Strong, Conductivity of, in Mixtures of Heavy and Light Water, A. Fink, P. Gross and H. Steiner, 44

Acta Physicochimica U.S.S.R., 217

Actinium, Radioactivity of, D. E. Hull, W. F. Libby and W. M. Latimer, 801

Activity Coefficients from Electromotive Forces, A. S. Brown and D. A. MacInnes, 611

Administration and Management, Problems of, Major L. Urwick; T. G. Rose; Dr. K. G. Fenelon, 651

Aeronautical Research, Recent, 1037

Africa: East and West, Ecological Expeditions in, 212, 213; Archæological Exploration in, Prof. L. Frobenius; Commander Nino del Grande, 213; 'Justice' in, 1003

Africae et Aegypti, Monumenta Cartographica, Quelques éclaircissements épars sur mes, Prince Youssouf Kamal (*Review*), 664

African: Music, Dr. E. von Hornbostel (*Review*), 3; Problems, Investigation of, 135; Bark Canoes, J. Hornell, 1031

Agranulocytic Angina, Dr. E. W. Adams, 72

Agricultural: Research Council, Dr. E. J. Butler appointed secretary to the, 218; Education, Higher, in Great Britain, 444; Situation, World, in 1933-34, 509; Research, Organisation of, 527; Dilemma: The, a Report of an Enquiry organised by Viscount Astor and Mr. B. Seebohm Rowntree (*Review*), 849; Production and National Nutrition, Dr. W. Gavin (*Review*), 849; Society, Central, of Great Britain and Ireland [1835], 963

Agriculture: British, Future of, Sir John Russell, 199; International Commission of, General Assembly of the, 367; State Control in, Financial and Economic results of, Dr. J. A. Venn, 387; Native, in Northern Rhodesia, C. G. Trapnell, 403

Aimol Kukis, Assam, Marriage among, J. K. Bose, 399

Aircraft, Heavier-than-Air, M. J. B. Davy. Second edition (*Review*), 816

Air: Transport, Economics of, H. Bouchée, 153; Raid Precautions: Handbook No. 2: Anti-Gas Precautions and First Aid for Air Raid Casualties, 489; Memorandum No. 1: Treatment of Casualties and Decontamination of Personnel, 489; Ionised, Dielectric Constant of, Prof. S. K. Mitra and S. S. Banerjee, 512; Viscosity of, and the Electronic Charge, Dr. G. Kellström, 682; -Conditioning in the Tropics, Prof. C. A. Middleton Smith, 905

Airy declines a Knighthood [1835], 923

Alaskan Archæology, Dr. A. Hrdlička, 918

Alchemist, A Musical, Prof. J. Read, 864

Alchemy: and Music, Prof. J. R. Partington; Prof. J. Read, 107; An Ancient Chinese Treatise on, Prof. J. R. Partington, 287; and Early Chemistry, Society for the study of, Foundation of and Election of Council, 1024

Alcohol and Road Accidents, 173

Aldrovanda vesiculosa, L., Opening and Closing Mechanism of the Leaf Blade of, Dr. J. Ashida, 519

d'Algèbre et de géométrie à l'usage des étudiants des Facultés des Sciences, Leçons, Prof. R. Garmer (*Review*), 973

Alicyclic Compounds, F. Pirrone (I), 526

Aliphatic Free Radicals, The, F. O. Rice and K. K. Rice (*Review*), 415

Allenic Compound, Resolution of an, E. P. Kohler, J. T. Walker and M. Tishler, 764

Alligator-Lizards in South-West America, H. S. Fitch, 480

All-India Institute of Hygiene and Public Health, Report for 1934, 545

Alpines, New, Dr. H. R. Smith, 441

Alternating Current Wave-Forms, Theory of, P. Kemp (*Review*), 594

Alumina, Adsorption of Grass and Butter Carotenes on, A. E. Gillam and M. S. El Ridi, 914

Aluminium: Hydroxide, Adsorption of, by Kieselguhr, Prof. E. C. C. Baly and W. P. Pepper, 28; Corrosion of, by Soda, Yeu Ki-Heng and Yeou Ta, 234; Pure, Recrystallisation of, J. Calvet, J. J. Trillat and M. Paic, 563; in Food, Dr. G. W. Monier-Williams, 961

'Amal' Bunsen Burner, 400

Amber in Palæolithic Times, Comte R. de Saint-Périer, 480

America: The New, the New World, H. G. Wells (*Review*), 414

American: Chemical Society, Official tercentenary of the, 307; Collecting Expeditions, 368; Ethnology, Bureau of, Fifty-first Annual Report, 508; Universities and Game-Rearing, J. N. Darling, 522; Democracy, The Obligation of the University to, S. P. Capan, 615; Museum, Prof. H. F. Osborn and the, 786; Aborigines, Racial Origins of the, Dr. A. Hrdlička, 875; Chemical Society, Function of the, Prof. W. A. Noyes, 1020

Amerindian Skulls, Primitive Traits in, Dr. A. Hrdlička, 543

Amines and Amides, Absorption Spectra in the near Infra-Red of, Mme. Marie Freymann and P. Rumpf, 769

Amino Acids: Raman Effect in Solutions of some, N. Wright and W. C. Lee, 300; Excreted by Leguminous Root Nodules, Chemical Nature of the, Prof. A. I. Virtanen and T. Laine, 756

Ammocœte Larva, Proteolytic Digestion in the, E. J. W. Barrington, 145

Ammonia, Liquid, and Tantalum Pentachloride, Mechanism of the reaction between, H. Moureu and C. Hamblet, 234

Ampère, impending centenary celebration of, 907

Amphibia, Induction of the Eye by a Specific Substance in the, G. Lopashov, 835

Amphioxus, Nerve Plexuses in, Dr. J. Poeke, 305

Amplifier Tubes, Quiet, G. L. Pearson, 1033

Anæmias, Treatment of, 430

Anaphylaxy from the point of view of Altitude, W. Kopaczewski and S. Marczewski, 731

Androstendione, Activity of, on the Sexual Organs of the Male Rat, Dr. E. Tschopp, 258

Anemometer, Suggested Totalising, for Oceanographers, Dr. J. N. Carruthers, 751

Angiospermy, The State of Flowering known as, Prof. J. McLean Thompson, 309
'Angle Dekkor', The, Adam Hilger, Ltd., 229
Animal: Hair, Spontaneous Super-contraction of, Dr. R. O. Hall, 28; Hairs, Fibre-forms in: H. J. Woods, 262; Dr. R. O. Hall, 478; Suffering, Relief of, Sir Frederick Hobday (Stephen Paget memorial lecture), 790; Parthenogenesis, A. D. Peacock, 845
Animal Year Book, III, 473
Animals: Extinct, Everyday Life of (*Review*), 492; New Classification of [1835], 1000
Annual Register, 1934, edited by Dr. M. Epstein (*Review*), 8
Antarctic: Research, Recent, undertaken by the Discovery Committee, 629; Discoveries, Admiral R. E. Byrd, 865; Moraines, Sir Douglas Mawson, 958
Anthracene, Hydrogenation of, A. Maillard, 81
Anthropology': 'Legislative, Dr. A. Macdonald, 507; A Hundred Years of, T. K. Penniman, 734; in Action: an Experiment in the Iringa District of the Iringa Province, Tanganyika, Dr. G. Gordon Brown and A. McD. Bruce Hutt (*Review*), 1004
Anti-Gas Precautions and First Aid for Air Raid Casualties, 329
Antillean Reptiles and Amphibia, List of, T. Barbour, 228
Antimony: Amorphous, Dr. J. A. Prins, 299; Doubly Ionised, Hyperfine Structure and the Gross Structure Analysis of the Spectrum of, Dr. J. S. Badami, 836
Anti-Smut Disinfection of the Seeds of Cereals, Mechanism of the Action of Heat in, R. Vanderwalle, 655
Apple Trees: Nutrition of, Effect of Rootstocks on the, L. G. G. Warne and Dr. T. Wallace, 35; Pruning of Mature, J. Oskamp, 763
Apples, Refrigerated Gas-storage of, Dr. F. Kidd and Dr. C. West, 556
Applied Mechanics, Fourth International Congress of, Proceedings of the, July 3-9, 1934 (*Review*), 8
Arable Soils, Contributions by the Atmosphere of Sulphur to, G. Bertrand, 487
Archæological: Research in Western China, 346; Exploration in Britain, Plan for funds for, Sir Frederic Kenyon, 428; Museums, 981; Research in South Africa, 998
Archæology: in South and East Africa, Prof. T. F. Dreyer, 872; of Rochford Hundred and South-East Essex, W. Pollitt, 906
Architect and Building Materials, Dr. R. E. Stradling, 903
Arctic, Capt. Back's return from the, [1835], 405
Argon: Nitrogen and, Solidification of, Prof. P. W. Bridgman, 36; The *L*-Emission Spectrum of, M. Bačkovský and Prof. V. Dolejšek, 643
Aristotle, Galileo and the Tower of Pisa, Prof. Lane Cooper (*Review*), 6
Aromatic Hydrocarbons, Ultra-Violet Absorption of certain, M. Pestemer and L. Wiligut (3), 44
Artemia salina, Adaptation in, 648
Asama-yaman (Japan) Eruption of 1935, T. Minakami, 877
Ascorbic Acid: Estimation of, by Titration, M. van Eekelen, 144; (Vitamin C), and the Germination and Growth of Seedlings, L. Havas, 435; Quantitative Determination of, A. L. Bacharach and H. E. Glynn, 757; Estimation of, by Titration, B. Ahmad, 797; (Vitamin C) and Phytocarcinomata, L. Havas, 989
Asia, Northern, Freshwater and Terrestrial Mollusca of, A. W. Mozley, 196
Asparagus Cultivation, A. N. Rawes, 958
Aspidiotus destructor, Sign. The Campaign against, in Fiji, T. H. C. Taylor (with three sections by R. W. Paine), 94
Association of Special Libraries and Information Bureaux, Twelfth Annual Conference of the, 139
Astrolabe, Use of the, Mme. Chandon and M. Gougenheim, 1023
Astronomical Union, International, Fifth General Assembly, 193
d'Astronomie, Dix leçons, E. Esclangon. Deux. édition (*Review*), 128
Astronomy, International Co-operation in, 193
l'Astrophysique, Problèmes actuels de, Prof. L. Houllevigue (*Review*), 205
Atlantic Ocean, Sediments in the, Dr. C. W. Correns; Dr. W. Schott, 305
Atmosphäre, Physik der, Vorlesungen über, late Prof. A. Wegener und Prof. K. Wegener (*Review*), 163
Atmosphere: Higher, Temperature Changes in the, Prof. E. V. Appleton, 52; Bacteriology of the, Prof. R. C. McLean (Chadwick lecture), 880; Lowest Layers of the, Transfer of Heat and Momentum in the, A. C. Best, 919
Atmospheric: Pollution, Twentieth Report on, 17; Visibility, W. E. K. Middleton, 36; Electricity, A New Theory of, R. Gunn, 74; Ozone, Determination of, by Fluorescein, W. Heller, 119; Physics, Prof. S. Chapman (*Review*), 163; Pollution, Sources of, Dr. R. Lessing, 651; Electricity, Prof. E. V. Appleton (Sir Halley Stewart Trust lecture), 711; Ozone, Measurement of the Reduced Thickness of, during the Polar Winter, D. Barbier, D. Chalonge and E. Vassy, 883; Condensation Nuclei, Diffusion Coefficients and Velocities of Fall in Air of, Prof. J. J. Nolan and V. H. Guerrini, 924
Atmospherics, Nature of, N. S. Subba Rao, 683
Atomic Physics: Dr. Max Born. Translated by Dr. J. Dougall; Prof. A. S. Eve (*Review*), 533; An Introduction to, Dr. J. Thomson (*Review*), 934
Atomiques, noyaux, Structure et propriétés des (*Review*), 663
Atoms, Adsorbed, Activation and Evaporation of, Prof. J. E. Lennard-Jones and C. Strachan, 267
Attention, Psychology of, I. Benson, 610
Auroral Display seen at Oxford [1835], 806
Australia: Commonwealth of, Council for Scientific and Industrial Research, Eighth Annual Report, 294; Radio Research in, 650; Commonwealth of, Official Year Book of the, 1934, 677; Archæology in, D. S. Davidson, 799
Australian: Institute of Agricultural Science, Journal of the, No. 1, 62; Woods, Identification of, W. E. Cohen; H. E. Dadswell and A. M. Eckersley, 481; Cowries, T. Iredale, 519
Avebury, Restoration at, 330
Aviation: International Control of, 489; Motor, A New Type of, F. Rochefort and J. Villey, 883

β-Decay, Recoil by, Dr. F. Bloch and Dr. C. Møller, 911
β-Rays, Use of Electron Lenses for, O. Klemperer, 726
β-Spectrum, Continuous, Disintegration Constant and the Upper Limit of the, Prof. G. J. Sizoo, 142
Beta: Processes and Nuclear Stability, Prof. G. Beck, 257; Ray Spectra of Artificially Produced Radioactive Elements, Prof. A. I. Alichanow, A. I. Alichanian and B. S. Dželepow, 258
Babylonia, Ancient, Methods of Orientation in, Dr. E. Unger, 763
Bacillus carotovorus, Jones, causing a Soft Rot of *Iris germanica* in Victoria, B. J. Grieve, 883
Back's, Capt., Arctic Expedition [1835], 616
Backward Peoples, Modern Production among, Dr. I. C. Greaves (*Review*), 854
Bacteria: The Biology of, an Introduction to General Microbiology, Prof. A. T. Henrici (*Review*), 51
Bacteriology: Experimental, in its applications to the Diagnosis, Epidemiology and Immunology of Infectious Diseases, Prof. W. Kolle and Prof. H. Hetsch. Translated by D. Erikson. English version, incorporating further revision, edited by Prof. J. Eyre. 2 Vols. (*Review*), 662; of the Atmosphere, Prof. R. C. McLean (Chadwick lecture), 880
Badianus Manuscript, The, an Aztec Herbal, Emily Walcott Emmart, 480
von Baeyer, Adolf, 1835–1917, Prof. J. R. Partington, 669
Baldness, Antagonistic Effect of Potassium Iodide in, due to Thallium Acetate, O. V. Hykeš and F. A. Diakov, 685
Baltic Countries, August, 471
Banana, Diseases of the, and of the Manila Hemp Plant, Dr. C. W. Wardlaw (*Review*), 5
Band-Spectra and Molecular Structure (*Review*), 887

Barnacles, Light as a Factor in the Growth of, Prof. A. B. Klugh and C. L. Newcombe, 992
Barkhausen Oscillator, F. B. Llewellyn, 442
Barley Leaves, Respiration of, E. W. Yemm, 266
Basutoland: Culture and Policy in, 121; Financial and Economic Position of, 121
Bay Islands' Culture, Honduras, Dr. W. D. Strong, 34
Beagle, H.M.S., crosses the Pacific [1835], 654
Beit: Memorial Fellowships for Medical Research, Prof. T. R. Elliott and Prof. E. D. Adrian appointed trustees; elections to fellowships, 100; Fellowships for Scientific Research, award of, 139
Belfast, Queen's University, conferment of honorary degrees, 117
Belgica, Zoology of the Voyage of the, L. Giltray; L. Černosvitov, 992
Belgique, Terrains, roches et fossiles de la, E. Maillieux. Deux. édition (*Review*), 357
Bell, Sir Charles, at the Middlesex Hospital [1835], 562; and his Edinburgh professorship [1835], 924
Benares Hindu University, College of Science, 674
Benzene, Structure of, Infra-Red Spectrum of Hexadeuterobenzene and the, Dr. W. R. Angus, C. R. Bailey, Prof. C. K. Ingold, A. H. Leckie, C. G. Raisin, J. W. Thompson and Dr. C. L. Wilson, 680
Be^8 and C^{12}, The Masses of, Dr. H. S. W. Massey and Dr. C. B. O. Mohr, 141
Beryllium: Nuclear γ-Radiation of, F. Koch and F. Rieder, 273; β-Radioactivity of, Absence of Natural E. Friedlander, 487
Berzelius in Paris [1835], 156
Benzylcarbonyl Chloride, Action of, on Insulin and other Proteins, W. E. Gaunt, G. Higgins and Dr. A. Wormall 438
Bibliothécaire, Rôle et formation du (*Review*), 280
Bihar Earthquake of 1934, The, J. B. Auden and A. M. N. Ghosh; N. Nasu, 485
Billingham Hydrogenation Plant, Opening of the, by Mr. Ramsay MacDonald, 635
Binary System, Orbit of a Third Invisible Body in a, F. Zagar, 526
Biochemical Progress (*Review*), 532
Biochemistry: Annual Review of, Edited by J. M. Luck. Vol. 4 (*Review*), 532; in Relation to Therapeutics, Sir Frederick Gowland Hopkins, 614
Bioklimatische Beiblätter der Meteorologischen Zeitschrift. Band 1, Heft 3, 61
Biological Classification, The Meaning of, Dr. W. T. Calman, 9
Biology at the Imperial Social Hygiene Congress, 116
Bird Sanctuaries in London, Report for 1934, 580
Birds, Daylight and the Feeding of, G. Marples, 188
Birkbeck College: Appeal for New Buildings, 615; Rebuilding, 787; Past, Present and Future, 819
Birmingham University: Col. H. F. Humphreys appointed professor of dental surgery, 524; Prof. K. N. Moss elected dean of the faculty of science; Dr. E. L. Hirst appointed reader in the chemistry of natural products, 881
Birth Control and its Opponents, Dr. F. W. White (*Review*), 458
Bismuth: Estimation of Small Percentages of, 332; Plasticity of, Dr. W. F. Berg and L. Sandler; Prof. E. N. da C. Andrade, 915
Blood: Serum under the influence of Heat, Physicochemical Study of the Changes Undergone by the, C. Achard and A. Boutaric, 42; -Sucking Diptera, Structure of the Proboscis in, B. Jobling, 145; B. Jobling, 990; S. K. Sen, 479; Coagulation of the, as a Chain Reaction, Dr. H. J. Fuchs, 184; Group Inheritance, Dr. J. Ff. Edwards and Dr. I. M. H. Etherington, 297; Prof. J. B. S. Haldane, 432; Dr. J. Ff. Edwards and Dr. I. M. H. Etherington, 646
Blue: Crab, Musculature of the, Miss Doris M. Coghran, 34; Pigment, A New, 862
Bog-flow in Co. Clare, a Recent, G. F. Mitchell, 963
Boiling Point of a Ternary System, Lowering of the, by Non-Volatile Substances, M. Centnerszwer and Mlle. M. Swierczewska, 845
Bombay Grasses, Blatter and McCann, 919
Bopyrids from Tanabe Bay, S. M. Shüno, 799
Boron Monoxide, β Bands of, A. Elliott, 617
Boscia rehmanniana, Pest., Stem Structure of, R. S. Adamson, 312
Bose Research Institute, Research at the, 556
Botanica, Chronica, Edited by Dr. F. Verdoorn. Vol. 1, 1935 (*Review*), 774
Botanical: Congress, Sixth International, Dr. A. B. Rendle, 612; Nomenclature, International Rules of, Dritte Ausgabe (*Review*), 699; Annual, A New (*Review*), 774
Botanist in the Garden, the, Sir Daniel Hall (*Review*), 931
Botany as an Experimental Science in Laboratory and Garden, Dr. Lilian J. Clarke (*Review*), 890; Experimental (*Review*), 890; A Century of, 1835–1885–1935, Prof. F. O. Bower, 938; 976
Botrytis spp., Relation of, to the 'Chocolate Spot' disease of Beans (*Vicia Faba*), A. R. Wilson, 226
Box Testing Laboratory, New, 905
Bozzolo, Colore del, C. Jucci, 271
Bradley's, F. H., Psychological Principles, Prof. G. Dawes Hicks (*Review*), 852
Brauner memorial lecture of the Chemical Society, Dr. S. I. Levy, 826
Breccias of Chassenon (Charente), Origin of the, F. Kraut, 406
Brinkley, Dr. John, Death of [1835], 447
British: Agriculture, Future of, Sir John Russell, 199; Association: at Dublin [1835], 196; 232; Norwich Meeting of the, 248; Sir Josiah Stamp elected president for 1936; other elections; places for future meetings; a Darwin Commemoration, 426; Seismological Committee, 544; Mathematical Tables, 580; 1936, appointment of sectional presidents, 980; Chemical Manufacturers' Association of: Dr. E. F. Armstrong elected president of the, 640; Nineteenth Annual Report, 674; Electrical and Allied Research Association Laboratory at Perivale, Opening of the, by the Duke of Kent, 673; Empire Naturalists' Association in Jersey, Summer Meeting, 214; Industries and their Organization, Prof. G. C. Allen. Second edition (*Review*), 322; Medical Association, Annual Meeting at Melbourne, 802; Museum: Bloomsbury, Recent acquisitions at the, 543; Etruscan Forgery in the, 752; (Natural History): Recent acquisitions at the, 176; Galapagos Exhibition at the, 506; Recent acquisitions at the, 712; 866; Plant Diseases, List of Common Names of, 216; Pyrenomycetes, Life-Histories of, C. G. C. Chesters, 441; Railways and Steamships in 1835, 843; School of Archæology in Jerusalem, P. L. O. Guy appointed director of the, 753; Scientific Instruments, Export of, to France, 601; Scientists of the Nineteenth Century, J. G. Crowther (*Review*), 50; Speleological Association, Formation of a; Sir Arthur Keith invited to become president, 178; Trees and Shrubs, Key to, C. T. Prime and R. J. Deacock, 473; Vertebrates, List of, 253; Waterworks Association, Annual Meeting, 39; Academy, Research and the, Prof. J. W. Mackail, 1022; Empire Cancer Campaign, Twelfth Annual Report, 1016; Film Institute, Second Annual Report, 1021; Museum, E. J. Forsdyke appointed director and principal librarian, 985
Broadcasting: and the Jubilee Naval Review, 97; in India, 231; Religious, at the Eucharistic Congress, 471
Bronns, Dr. H. G., Klassen und Ordnungen des Tier-Reich wissenschaftlich dargestellt in Wort und Bild: Band 5: Arthropoda. Abt. 4: Arachnoidea und kleinere ihnen nahegestellte Arthropodengruppen. Buch 4: Solifuga, Palpigrada. C. Fr. Roewer. Lief. 1. Lief. 2. Lief. 3. Lief. 4. Lief. 5 (Schlusslieferung des 4 Buches). Leif. 1–5; Band 4: Vermes. Abt. 2: Aschelminthen. Buch 1: Rotatorien, Gastrotrichen und Kinorhynchen. Bearbeitet von A. Remane. Lief. 2 (Rotatorien). Lief. 3 (Rotatorien). Lief. 4 (Rotatorien); Band 3: Mollusca. Abt. 3: Bivalvia. F. Haas. Lief. 4; Band 3: Mollusca (Weichtiere). Abt. 2: Gastropoda. Buch 3: Opisthobranchia. H. Hoffmann. Lief. 1, 622

Bronze, Origin of, Prof. C. H. Desch, 342
Brussels University, Dr. E. Renaux nominated professor of bacteriology, 923
Budapest University, tercentenary of, conferment of honorary degrees on Sir Charles Sherrington and Sir F. Gowland Hopkins, 729
Bufo vulgaris, Larvæ of, Action of Bromine on the Growth and Metamorphosis of the, V. Famiani, 1040
Building Research, Progress of, 1035
Bull Frog Retina, Pigments of the, G. Wald, 832
Bureau of Standards, Washington, Work of the, 270
Burma, Natural Gas Resources of, C. T. Barber, 611
Burnett, Gilbert Thomas, Death of [1835], 156
Business Training, Universities and, Dr. J. A. Bowie, 691
Butomopsis lanceolata, Kunth, Life-History of, B. M. Johri, 338
Butter Carotenes, Grass and, Adsorption of, on Alumina, A. E. Gillam and M. S. el Ridi, 914; Catalase Test to, Application of the, G. Cruess-Callaghan, 963
Butyl Alcohol in certain Fusel Oils, Presence of active secondary, R. Dulou, 81

Cacao: The Diseases and Curing of, Prof. H. R. Briton-Jones (*Review*), 5; Cultivation, Problems of, Sir Geoffry Evans, 556
Calanus finmarchicus, Researches on, 342
Calcite, Thermal Expansion of, H. Saini, 273
Calcium: Quasi-Molecules of, in Dwarf Stars of Type *M*, Absorption Continuum due to, Prof. B. Lindblad, 67; Carbide, Action of, on Methyl Alcohol, Prof. A. Contardi and Dr. B. Ciocca, 190; Fluorine and, Induced Radioactivity of, Dr. O. R. Frisch, 220
Calculus, The, Prof. H. H. Dalaker and Prof. H. E. Hartig. Third edition (*Review*), 892
Cambridge: Fens, Archæology in the, 290; Philosophical Society, election of officers, 791; Rocking Microtome, Jubilee of the, 256; Solar Physics Observatory, Twenty-third Annual Report, 906; University: gift by Sir John D. Siddeley; award of the Harkness scholarship to Miss D. H. Rayner; the Frank Smart prizes to M. F. Mare, D. W. Ewer and R. S. Sturdy, 79; F. R. Parrington appointed demonstrator in zoology; Dr. R. Knox and Dr. G. P. McCullagh appointed demonstrators in pathology; award of the Marmaduke Shield scholarship to G. W. Harris; gift by Rev. J. H. T. Perkins, 233; Dr. J. A. Ryle, appointment as regius professor of physic in, 447; resignations and retirements; R. Passmore elected Gwynaeth Pretty student and Dr. M. E. Adair John Lucas Walker student; E. D. Ward awarded the John Wimbolt prize, 524; Dr. J. A. Ryle appointed regius professor of physic; H. Cary Gilson, N. M. V. Rothschild and H. W. Melville elected fellows of Trinity College; Dr. G. B. B. M. Sutherland elected a fellow and appointed lecturer and director of studies in physical sciences at Pembroke College, 654; D. H. Valentine appointed Frank Smart university student in botany; Prof. A. Hutchinson, Prof. J. Graham Kerr, Prof. G. H. F. Nuttall and Dr. A. W. Rogers elected honorary fellows of Christ's College; acceptance of Sir John Siddeley's gift for aeronautical research, 692; grant from the Balfour Fund to F. R. Parrington, 730; Dr. T. S. Hele elected master of Emmanuel College; P. H. Blair appointed an assistant lecturer in archæology and anthropology in, 768; proposed memorial to Prof. J. E. Marr; plans for a new High-tension Laboratory for the Cavendish Laboratory, 805; J. D. Boyd elected a fellow of Clare College, 881; N. G. Hentley appointed Benn W. Levy research student in biochemistry; Sir C. J. H. Thomas elected an honorary fellow of Queens' College; C. W. Gilbert elected a research fellow of Jesus College, 962; J. A. G. Haslam recommended for appointment as assistant in research in the sub-department of aeronautics, 1000
Camionale Genoa-Serravalle for Lorry Traffic, The, 62
Canadian Mineral Industry in 1934, 473
Cancer: Cell, Proteins of the, C. Achard and M. Piettre, 883; Recent Research on, 1016
Cape Province, Organic Matter Content and Carbon-Nitrogen Ratios of Some Semi-Arid Soils of the, W. E. Isaac and B. Gershill, 157
Carbohydrates: Molecular Structure of, Prof. W. N. Haworth, 380; Prof. W. N. Haworth and others, 767
C^{12}, Be^{8} and, The Masses of, Dr. H. S. W. Massey and Dr. C. B. O. Mohr, 141
Carbon: Tetrachloride Vapour, Diffraction of X-Rays and Electrons by, C. Degard, J. Piérard and Dr. W. van der Grinten, 143; Suboxide, Preparation of, A. Klemenc, R. Wechsberg and G. Wagner, 450; Heat of Sublimation of, Dissociation Energy of Carbon Monoxide and the, H. Lessheim and Prof. R. Samuel, 606; Monoxide: Dissociation Energy of, and the Heat of Sublimation of Carbon, H. Lessheim and Prof. R. Samuel, 606; Dissociation Energy of, F. Brons, 796; Energy of Dissociation of, P. Goldfinger, W. Lasareff and B. Rosen, 1002
Carbonic Oxide-Oxygen Mixtures, Moist, Flame Speeds during the Inflammation of, Dr. W. Payman and Prof. R. V. Wheeler, 1028
Carcinogenic Hydrocarbons, Synthesis and Biological Effects of, Prof. J. W. Cook (Bedson lecture), 788
Cargo Ship and Tanker Development, J. McGovern, 129
Carlsberg Foundation's Oceanographical Expedition Round the World 1928–30, etc.; Dana Report, No. 1, etc., 445
Carnegie Endowment for International Peace, Division of Intercourse and Education, Report for 1934, Dr. N. Murray Butler, 309
Carob Flour as a Foodstuff, Prof. A. Valenti, 190
Carotenoid Pigments in Fishes, F. B. Sumner and D. L. Fox (3), 407
Carotid Gland of the South African Bullfrog, Dr. G. Eloff, 108
Carr and Price Reaction of the Fatty Acids of Cod Liver Oil after Vigorous Saponification, The, A. Emmerie, 183
Cars go Out of Control: How, an Analysis of the Driver's Reflexes, Prof. Y. Henderson, 864
γ Cassiopeiæ, Spectrum of, Changes in the, Dr. W. J. S. Lockyer, 151; 916
Cat, Wild, and Domestic Cat, J. C. Kirk, 992
Catalysis, Heterogeneous, Kinetics of, and of Enzyme Action, Prof. E. C. C. Baly, 146
Catalytic Decomposition of Hydrocarbons, Effect of Adsorbed Water on the (by a Molecular Beam Method), O. Beeck, 1028
Catatonia, Surgical, H. de Jong and A. Gallinek, 235
Catfish, Common, Breeding Habits of, C. M. Breder, 838
Cathode, The Oxide-coated, M. Benjamin, 306
Cathodic Phosphorescence, Some Phenomena of, M. Servigne, 157
Cave Exploration: R. de Joly, 430; in Britain, Recent, 648
Cellulose: Nitration of, by Nitric Anhydride, R. Dalmon, J. Chédin and L. Brissaud, 807; Pulp, 1014
Celsius, Linnæus and the Centigrade Thermometer, Dr. N. V. Nordenmark, 365
Census Statistics, 1931, 255
Ceratolepis hamata, Localisation in the Intermediate Waters of the Pacific of the little-known, L. Fage, 43
Ceratium, Biology and Variation of, 445
Cerin and Friedelin, N. L. Drake and R. P. Jacobsen, 726
Ceylon: Marine Biology in, A. H. Malpas, 471; Geology of, J. S. Coates, 556
Chemical: Induction, A. Skrabal, 44; Industry, Past and Future of, Dr. E. F. Armstrong (Medallist's address to the Society of Chemical Industry), 212; Thermodynamics, The Fundamentals of, Dr. J. A. V. Butler. Part 1: Elementary Theory and Electrochemistry. Second edition (*Review*), 244; Industry, Society of, American section of the, presentation of the Chemical Industry medal to Dr. E. R. Weidlein, 789; Formulary, The. Editor-in-chief: H. Bennett. 2 Vols. (*Review*), 816

Chemie : -Ingenieur, Der, Herausgegeben von A. Eucken und M. Jakob. Generalregister für Band 1-2 (*Review*), 625 ; organischen, Theoretische Grundlagen der, Prof. W. Hückel. Band 2. Zweite Auflage (*Review*), 702
Chemischen Physik, Hand- und Jahrbuch der, Herausgegeben von A. Eucken und K. L. Wolf. Band 1, Abschnitt 1 : Theorien des Aufbaues der Materie. 1 : Die Grundlagen der Quantentheorie, H. A. Kramers ; Band 6, Abschnitt 2 : Elektrische Leitfähigkeit. A : Gase, W. Hanle ; B : Flüssigkeiten und Lösungen, H. Ulich ; C : Nichtmetallische Kristalle, W. Flechsig ; Band 6, Abschnitt 3 : Positive Korpuskularstrahlen. A : Verhalten von Alpha-Strahlen bein Durchgang durch Materie, H. Pose ; B : Kanalstrahlen und ihre Wechselwirkung mit Materie (einschliesslich Massenspektroskopie), R. Wierl ; Band 9 : Die Spektren Entstehung und Zusammenhang mit der Struktur der Materie. Abschnitt 1 : Atomspektren, H. Kuhn (*Review*), 125 ; Band 6, Abs. 1A, J. Hengstenberg und K. Wolf (*Review*), 778 ; Band 6, Abs. 1B, O. Fuchs und K. L. Wolf (*Review*), 816
Chemisches, Anorganisch, Praktikum, Prof. W. Manchot (*Review*), 739
Chemist, The, and the Community, W. M. Ames, 83

Morgan, 230 ; Applied : Origins and Development of, Prof. J. R. Partington (*Review*), 277 ; The Beginnings of, Dr. J. W. Mellor (*Review*), 277 ; Physical, Experimental, Prof. F. Daniels, Prof. J. H. Mathews and Prof. J. W. Williams. Second edition (*Review*), 495 ; Surface : Dr. N. K. Adam, 499 : Photoelectricity and, A. H. Wilson (*Review*), 589 ; Teaching of, N. F. Newbury (*Review*), 593 ; of Antiquities, Prof. J. R. Partington, 688 ; Inorganic, An Introduction to, Dr. S. Prakash (*Review*), 778 ; Teaching of, Prof. A. Smithells (Harrison memorial lecture), 788 ; Organic, A Text-Book of, Historical, Structural and Economic, Prof. J. Read. Second edition (*Review*), 891 ; Elementary Textbook of, with Laboratory Experiments, J. J. Guenther (*Review*), 892
Cheshunt Experimental Station, Twentieth Annual Report, 294
Chesney's, Col., Expedition, Progress of, [1835], 118
Chicago University, gift to, by the Rockefeller Foundation, 431
Chicks, Dietary Hæmorrhagic Disease in, H. J. Almquist and E. L. R. Stokstad, 31
China : Reptiles of, Turtles, Crocodilians, Snakes, Lizards, C. H. Pope (*Review*), 204 ; Scientific Research in, the Academic Sinica, V. K. Ting, 208 ; Tectonic Framework of, Prof. J. S. Lee, 268 ; Science *v.* Superstition in, 310 ; Western, Archæological Research in, 346
China's Geographic Foundations : a Survey of the Land and its Peoples, Dr. G. B. Cressey (*Review*), 533
Chinese : Loess Deposits, Prof. G. B. Barbour, 150 ; Starling in America, T. H. Scheffer and C. Cottam, 227 ; Art : Edited by Leigh Ashton (*Review*), 854 ; International Exhibition of, 878
Chirocephalus, Function of the Labral Glands in : Miss K. W. Nicholson and Prof. C. M. Yonge, 608 ; Prof. H. G. Cannon, 758
Chloropentammine Cobaltic Chloride, Redetermination of the Solubility of, F. J. Garrick, 1027
Choline Esters, Unstable, in Invertebrates, Occurrence of, Dr. Z. M. Bacq, 30
Christian : Art, Early, in the British Isles, J. B. Calkin, 155 ; Doctrine, Human Origin and, Dr. W. D. Lang, 168
Chromatophores ? What Are the Resting and the Active States of, G. H. Parker, 197
Chromosome : Micelle, the, and the Banded Structure of Chromosomes in the Salivary Gland, Dr. Dorothy M. Wrinch, 68 ; Conjunction, Homologous Loci and, Forces of Attraction of, Dr. B. N. Sidorov, N. N. Sokolov and I. E. Trofimov, 108 ; Behaviour and Protein Pattern, 786 ; Disjunction, Crossing Over and, Dr. S. Gershenson, 834 ; Dr. C. D. Darlington, 835
Ciliate Protozoa from the Cæcum of the Indian Elephant, Two Remarkable, C. A. Kofoid, 488
Cinema : Industry, a Statistical Survey of the, S. Rowson, 983 ; in Education, the, a Handbook for Teachers, D. C. Ottley (*Review*), 1007
Cinematograph and the School, the (*Review*), 1007
Cinematography : Lumière and the Invention of, 803 ; Technicolor Process of, Lenses Employed in the, H. W. Lee, 879
Citizenship, Chemistry and, 83
Citrus, Genus, Mycorrhizal Habit in the, Dr. M. C. Rayner, 516
Civil : Engineers, Institution of : Awards of the, 715 ; *Journal* of the, 865 ; Service Examinations, Everyday Science in, Dr. H. Dingle, 866
Civilisation : and the Growth of Law, Dr. W. A. Robson (*Review*), 815 ; and its "Crises", F. S. Marvin (*Review*), 1008
Civilization, The Source of, G. Heard (*Review*), 1008
Cladocera, Japanese Freshwater, Dr. M. Uéno, 918
Cleopatra's Temple at Armant, Sir Robert Mond and O. H. Myers, 798
Cliff Scenery, Preservation of, Dr. Vaughan Cornish, 637
Coal : Geological Research on, Prof. H. G. A. Hickling, 381 ; Some Geological Aspects of Recent Research on, Prof. H. G. A. Hickling, 817 ; Resources, Our Nation's, Sir Harold Hartley, 828 ; Hydrogenation : of, 855 ; the Development of, by Imperial Chemical Industries, Ltd., K. Gordon, 855 ; Some Geological Aspects of Recent Research on, Prof. H. G. A. Hickling, 858 ; -Miner, Energy Output of the, Prof. K. N. Moss, 998
Coalescence in Stages Between Two Drops of a Liquid, Dr. I. W. Wark and A. B. Cox, 182 ; Dr. M. Katalinic, 915
Coals, the Classification of, Dr. Marie C. Stopes, 33
Cobalt : Amalgam, Oxidation of, F. P. Dwyer and J. W. Hogarth, 693 ; Wire, Treated, Abnormal Magnetic Behaviour of, Dr. T. F. Wall, 397 ; Nickel and, Induced Radioactivity of, J. Rotblat, 515
Coconut Scale in Fiji, Biological Control of, Dr. A. D. Imms, 94
Cod Liver Oil : the Carr and Price Reaction of the Fatty Acids of, After Vigorous Saponification, A. Emmerie, 183 ; Toxicity of, L. L. Madsen, C. M. McCay and L. A. Maynard, 1033
Coffee Plantations, the Climate and Eco-climates of, T. W. Kirkpatrick, 111
Coir, Sisal and Oak, Molecular Structure in, Dr. E. N. Miles Thomas and J. Hewitt, 69
Colbatch, Sir John, Prof. D. F. Fraser-Harris, 291
Colchester : Excavation at, 251 ; Further Discoveries at, 330 ; Romano-Celtic Temple at, 427
Cold Spring Harbor, N.Y., Genetics at, 446
Cold-storage Plant in Madrid, O. Rhunke, 138
Coleoptile Growth as Affected by Auxin, Aging and Food, F. W. Went, 617
College Library Administration in Columbia, Missouri, 405
Colloid Osmotic Pressure of the Body Fluids of Marine Animals, Dr. P. Meyer, 757
Colloidal Solutions, Metallic and Organic, Absorption Spectra of, and the Absorption of Metallic Films, A. T. Williams, 807
Colloids : Swelling of, Prof. H. Staudinger and E. Husemann, 523 ; Thixotropic, Prof. H. Freundlich, 922 ; Chemical Action caused by Neutrons and Gamma Rays and the Effects of these Agents on, Prof. F. L. Hopwood and J. T. Phillips, 1026
Colonial Office Appointments, 64 ; 256 ; 431 ; 602 ; 791 ; 949
Colorado, U.S.A., Stone Age Culture in, Dr. F. H. H. Roberts, Jr., 903
Colorimeter, A New Type of, J. Wouda, 235

Colour: of the Positive After-Image of a Colour, Dr. F. W. Edridge-Green, 302; Reactions of Tartaric, Citric and Aconitic Acids, O. Fürth and H. Herrmann, 450
Columbus, Landfall of: Lieut.-Comdr. R. T. Gould, 559; Possible Bearing of a Luminous Syllid on the Question of the, L. R. Crawshay, 559
Combustion Research, Fifty Years of, Prof. W. A. Bone (William Young memorial lecture), 637
Commonwealth Fund Trustees, Report for 1935, 805
CO Molecule, Dissociation Energy of the, B. Rosen, 226
Company Promotion, Exploitation of Science in, 861
Complex: Numbers, Graphical Representation of, W. F. Floyd, 224; Compounds, C. Duval, 234
Condensation Reactions, Polymerisation and, Prof. E. K. Rideal, 626;
Conduct, a Psychology of (*Review*), 585
Conifers: Pollination Mechanism in, Prof. J. Doyle and Miss Mary O'Leary, 40; in New Zealand, Aphomopsis Disease of, T. T. C. Birch, 189; of the Balipara Frontier Tract, Assam, Dr. N. L. Bor, 230
Constants: Annual Tables of, 17; in Use in Physics, Meaning of Certain, late Sir Richard T. Glazebrook, 986
Constellations, A Guide to the, Prof. S. G. Barton and Prof. W. H. Barton, Jr. Second edition (*Review*), 89
Consumers, The Outlook for, 1019
Consumption in Man and Animals, [1835], 405
Continents, Form, Drift, and Rhythm of the, Prof. W. W. Watts, 369
Cookery: A New Technique in, A. F. Dufton, 796; R. O. Hall and L. Hall, 955
Cooke's Illustrations of British Fungi, Index to, A. A. Pearson, 546
Co-operative Buying, 428
Co-zymase, Oxidative Inactivation of, with Schardinger Enzyme Preparations, Dr. F. Lipmann, 913
Copepod Habitat, a New and Important, C. B. Wilson, 1031
Copepods: Adriatic, Malformation in, Dr. F. Früchtl, 724; Calanoid, Swimming and Feeding of Certain, A. G. Lowndes, 800
Copper: Minerals of Kinsenda (Belgian Congo), M. Gysin (2), 81; Magnetism of, Prof. S. R. Rao, 436; Properties of, Influence of Sulphur on the, W. Broniewski and W. Lewandowski, 448; Oxide Films Showing Interference Colours, Electrical Conductivity of, Prof. F. H. Constable, 517; Deposits, Origin of, C. S. Ross, 876; Electrolytic Deposit of, Practically Instantaneous Action of Certain Colloids on the, P. Jacquet, 1001; and Ammonium, Crystalline Parameters of the Double Bromide of, A. Silberstein, 1002; -Beryllium Alloys, Modulus of Elasticity of the, L. Guillet, Jr., 1002; Sulphate, Pentahydrated, Decomposition of, by Heat, O. Binder, 1038
Coprosterol, Precursors of, and the Bile Acids in the Animal Organism, Dr. O. Rosenheim and T. A. Webster, 474
Corn, the Growth Hormone and the Dwarf Type of Growth in, J. Van Overbeek, 197
Cornish: Pumping Engine, Trial of a, [1835], 806; Engines Preservation Fund, 829
Corpus: Luteum Hormone, Nomenclature of, Dr. W. M. Allen, Prof. A. Butenandt, Prof. G. W. Corner and K. H. Slotta, 303; Allatum of Insects, Functions of the, Dr. V. B. Wigglesworth, 338
Corophium curvispinum, G. O. Sars, var. *devium*, Wundsch, in England, G. I. Crawford, 685

CORRESPONDENCE

α-Particle: Single, Registration of the Ionisation Curve of a, Dr. H. Alfvén, 70; Registration of the Ionisation Curve of a Single, Prof. G. Stetter, Dr. H. Alfvén, 394
Acetylcholine and Sterols in Tissues, Interaction Between, Dr. G. S. Carter and Dr. L. W. Mapson, 143
Air: Ionised, Dielectric Constant of, Prof. S. K. Mitra and S. S. Banerjee, 512; Viscosity of, and the Electronic Charge, Dr. G. Kellström, 682
Alchemy and Music, Prof. J. R. Partington; Prof. J. Read, 107
Alumina, Adsorption of Grass and Butter Carotenes on, A. E. Gillam and M. S. El Ridi, 914
Aluminium Hydroxide, Adsorption of, by Kieselguhr, Prof. E. C. C. Baly and W. P. Pepper, 28
Amino Acids: Raman Effect in Solutions of Some, N. Wright and W. C. Lee, 300; Excreted by Leguminous Root Nodules, Chemical Nature of the, Prof. A. I. Virtanen and T. Laine, 756
Ammocœte Larva, Proteolytic Digestion in the, E. J. W. Barrington, 145
Amphibia, Induction of the Eye by a Specific Substance in the, G. Lopashov, 835
Androstendione, Activity of, on the Sexual Organs of the Male Rat, Dr. E. Tschopp, 258
Animal: Hair, Spontaneous Super-Contraction of, Dr. R. O. Hall, 28; Hairs, Fibre-forms in: H. J. Woods, 262; Dr. R. O. Hall, 478
Antimony: Amorphous, Dr. J. A. Prins, 299; Doubly Ionised, Hyperfine Structure and the Gross Structure Analysis of the Spectrum of, Dr. J. S. Badami, 836
Archæology in South and East Africa, Prof. T. F. Dreyer, 872
Argon, the *L*-Emission Spectrum of, M. Bačkovský and Prof. V. Dolejšek, 643
Ascorbic Acid: Estimation of, by Titration, M. van Eekelen, 144; (Vitamin C) and the Germination and Growth of Seedlings, L. Havas, 435; Quantitative Determination of, A. L. Bacharach and H. E. Glynn, 757; Estimation of, by Titration, B. Ahmad, 797; (Vitamin C) and Phytocarcinomata, L. Havas, 989
Atmospherics, Nature of, N. S. Subba Rao, 683
β-Decay, Recoil by, Dr. F. Bloch and Dr. C. Møller, 911
β-Spectrum, Continuous, Disintegration Constant and the Upper Limit of the, Prof. G. J. Sizoo, 142
Beta: Processes and Nuclear Stability, Prof. G. Beck, 257; Ray Spectra of Artificially Produced Radioactive Elements, Prof. A. I. Alichanow, A. I. Alichanian and B. S. Dželepow, 257
Be^8 and C^{12}, The Masses of, Dr. H. S. W. Massey and Dr. C. B. O. Mohr, 141
Baldness, Antagonistic Effect of Potassium Iodide in, due to Thallium Acetate, O. V. Hykeš and F. A. Diakov, 685
Beans (*Vicia Faba*), 'Chocolate Spot' Disease of, Relation of *Botrytis* spp. to the, A. R. Wilson, 226
Benzene, Structure of, Infra-Red Spectrum of Hexadeuterobenzene and the, Dr. W. R. Angus, C. R. Bailey, Prof. C. K. Ingold, A. H. Leckie, C. G. Raisin, J. W. Thompson and Dr. C. L. Wilson, 680
Benzylcarbonyl Chloride, Action of, on Insulin and Other Proteins, W. E. Gaunt, G. Higgins and Dr. A. Wormall, 438
Bismuth, Plasticity of, Dr. W. F. Berg and L. Sandler; Prof. E. N. da C. Andrade, 915
Blood: Coagulation of the, as a Chain Reaction, Dr. H. J. Fuchs, 184; Group Inheritance: Dr. J. Ff. Edwards and Dr. I. M. H. Etherington, 297; Prof. J. B. S. Haldane, 432; Dr. J. Ff. Edwards and Dr. I. M. H. Etherington, 646; -Sucking Diptera: Structure of the Proboscis in, B. Jobling, 145, 990; S. K. Sen, 479
Botrytis spp., Relation of, to the 'Chocolate Spot' Disease of Beans (*Vicia Faba*), A. R. Wilson, 226
Bull Frog Retina, Pigments of the, G. Wald, 832
Butomopsis lanceolata, Kurth, Life-History of, B. M. Johri, 338
Butter Carotenes, Adsorption of Grass and, on Alumina, A. E. Gillam and M. S. El Ridi, 914
C^{12}, Be^8, The Masses of, Dr. H. S. W. Massey and Dr. C. B. O. Mohr, 141
CO Molecule, Dissociation Energy of the, B. Rosen, 226
Calcium: in Dwarf Stars of Type *M*, Absorption Continuum Due to Quasi-Molecules of, Prof. B. Lindblad, 67; Fluorine and, Induced Radioactivity of, Dr. O. R. Frisch, 220

Carbon: Tetrachloride Vapour, Diffraction of X-Rays and Electrons by, C. Degard, J. Piérard and Dr. W. van der Grinten, 142: Heat of Sublimation of, Dissociation Energy of Carbon Monoxide and the, H. Lessheim and Prof. R. Samuel, 606; Monoxide, Dissociation Energy of: and the Heat of Sublimation of Carbon, H. Lessheim and Prof. R. Samuel, 606; F. Brons, 796
Carbonic Oxide-Oxygen Mixtures, Moist, Flame Speeds during the Inflammation of, Dr. W. Payman and Prof. R. V. Wheeler, 1028
Carotid Gland of the South African Bullfrog, Dr. G. Eloff, 108
Carr and Price Reaction of the Fatty Acids of Cod Liver Oil after Vigorous Saponification, the, A. Emmerie, 183
γ-Cassiopeiæ, the Spectrum of, Dr. W. J. S. Lockyer, 916
Catalysis, Kinetics of Heterogeneous, and of Enzyme Action, Prof. E. C. C. Baly, 146
Catalytic Decomposition of Hydrocarbons, Effect of Adsorbed Water on the (by a Molecular Beam Method), O. Beeck, 1028
Chicks, Dietary Hæmorrhagic Disease in, H. J. Almquist and E. L. R. Stokstad, 31
Chirocephalus, Function of the Labral Glands in: Miss K. W. Nicholson and Prof. C. M. Yonge, 608; Prof. H. G. Cannon, 758
Chloropentammine Cobaltic Chloride, Redetermination of the Solubility of, F. J. Garrick, 1027
Choline Esters, Unstable, in Invertebrates, Occurrence of, Dr. Z. M. Bacq, 30
Chromosome: Micelle, the, and the Banded Structure of Chromosomes in the Salivary Gland, Dr. Dorothy M. Wrinch, 68; Conjugation, Homologous Loci, Forces of Attraction of, Dr. B. N. Sidorov, N. N. Sokolov and I. E. Trofimov, 108; Disjunction, Crossing-over and, Dr. S. Gershenson, 834; Dr. C. D. Darlington, 835
Citrus, Mycorrhizal Habit in the Genus, Dr. M. C. Rayner, 516
Cleopatra's Temple at Armant, Sir Robert Mond and O. H. Myers, 798
Coalescence in Stages Between Two Drops of a Liquid, Dr. I. W. Wark and A. B. Cox, 182; Dr. M. Katalinic, 915
Coals, The Classification of, Dr. Marie C. Stopes, 33
Cobalt: Wire, Treated, Abnormal Magnetic Behaviour of, Dr. T. F. Wall, 397; Nickel and, Induced Radioactivity of, J. Rotblat, 515
Cod Liver Oil, the Carr and Price Reaction of the Fatty Acids of, after Vigorous Saponification, A. Emmerie, 183
Coir and Oak, Sisal, Molecular Structure in, Dr. E. N. M. Thomas and J. Hewitt, 69
Colloid Osmotic Pressure of the Body Fluids of Marine Animals, Dr. P. Meyer, 757
Colloids, Chemical Action Caused by Neutrons and Gamma Rays and the Effects of these Agents on, Prof. F. L. Hopwood and J. T. Phillips, 1026
Colour of the Positive After-Image of a Colour, Dr. F. W. Edridge-Green, 302
Complex Numbers, Graphical Representation of, W. F. Floyd, 224
Constants, Certain, in use in Physics, Meaning of, late Sir Richard T. Glazebrook, 986
Cookery, a New Technique in, A. F. Dufton, 796; R. O. Hall and L. Hall, 955
Coprosterol, Precursors of, and the Bile Acids in the Animal Organism, Dr. O. Rosenheim and T. A. Webster, 474
Copper: Magnetism of, Prof. S. R. Rao, 436; Oxide Films Showing Interference Colours, Electrical Conductivity of, Prof. F. H. Constable, 517
Corophium curvispinum, G. O. Sars, var. *devium*, Wundsch, in England, G. I. Crawford, 685
Corpus: Luteum Hormone, Nomenclature of, Dr. W. M. Allen, Prof. A. Butenandt, Prof. G. W. Corner and K. H. Slotta, 303; Allatum of Insects, Functions of the, Dr. V. B. Wigglesworth, 338
Cosmic: Rays, Nova Herculis and, Dr. A. K. Das, 29; Ray: Bursts in Liquid Dielectrics, Prof. C. Białobrzeski and I. Adamczewski, 109; Intensity, Diurnal Variation of, and Nova Herculis, Dr. F. Barnóthy and Dr. M. Forró, 680; Radiation, Primary, Positive and Negative Ions in the, H. J. Walke, 681; Rays, Vertical Intensity of, by Threefold Coincidences in the Stratosphere, Prof. E. Regener and G. Pfotzer, 718; Ray Showers at a Considerable Depth below Ground-level, Production of, D. H. Follett and J. D. Crawshaw, 1026
Co-zymase, Oxidative Inactivation of, with Schardinger Enzyme Preparations, Dr. F. Lipmann, 913
Crossing-Over and Chromosome Disjunction, Dr. S. Gershenson, 834; Dr. C. D. Darlington, 835
Crystal Grown by the Bridgman Method, Sub-Boundaries in a, Dr. W. H. George, 392
'*Culex pipiens*' (Diptera, Culicidæ), 'Autogenous' Strains of, J. F. Marshall and J. Staley, 641
Cyclohexane Rings, Multiplanar: Prof. M. Qudrat-i-Khuda, 301; Dr. R. D. Desai and Prof. R. F. Hunter, 608; 953
Czechoslovakia, Oil-Waters in, Radioactivity of, Prof. F. Běhounek, V. Santholzer and Prof. F. Ulrich, 910
Darwin, Charles, and the Galapagos Islands, Mrs. Nora Barlow, 391
Deafness, Experimental, A. F. Rawdon-Smith, 32
Deep Sea Mud, Celluloid Tubes for Sampling Cores of, N. J. Tarasov, 263
Dementia nomenclatorica americana, E. Heron-Allen, 797
Dental Caries in Prehistoric South Africans, Prof. T. F. Dreyer, 302
Depigmentation, a New Dietary Deficiency Disease, cured by Copper, Dr. F. J. Gorter, 185
Deuterium, Enzyme Catalysis of the Exchange of, with Water, G. H. Bottomley, Dr. B. Cavanagh and Prof. M. Polanyi, 103
Diamagnetic Susceptibilities, Effect of Light on, H. C. Bhuyan, 872
Dibenzanthracene, Lecithin as a Dispersing Agent for, H. D. Barnes, 756
Dielectric Constant of Ionised Air, Prof. S. K. Mitra and S. S. Banerjee, 512
Dietary Hæmorrhagic Disease in Chicks, H. J. Almquist and E. L. R. Stokstad, 31
Dioxane, Extreme Infra-Red Adsorption of D_2O, Ice and D_2O in, G. H. Cartwright, 181
Dipterocarpaceæ-Dipterocarpoideæ in Africa, Occurrence of the, Dr. J. Burtt Davy, 991
Discoveries, the Accessibility of, Sir Joseph Larmor, 722
Domestic Heating, Ventilation and, Sir Leonard Hill; the Writer of the Note, 225; 339
Duodenum, An Insulin Inhibiting Agency in the, Prof. A. B. Macallum, 32
Dysprosium and Other Rare Earth Elements, Artificial Radioactivity of, Prof. G. Hevesy and Miss Hilde Levi, 103
Earthquakes, Deep-focus, A New Wave Characteristic of, R. C. Hayes, 337
Egg Case in the Crustacea, Origin and Nature of the, Prof. C. M. Yonge, 67
Electric Currents Flowing Over Rusting Iron, the, Dr. U. R. Evans, 792
Electrical Units and the I.E.C., Sir Richard T. Glazebrook, 71; 110; Dr. N. R. Campbell, 148
Electromagnetic Waves, Negative Attenuation of, and Sommerfeld's Theory of Ground Absorption, Dr. S. R. Khastgir, D. H. Chandhuri and B. Sen Gupta, 605
Electron: Pairs, Production of, Prof. G. Racah, 393; Diffraction: by Vitreous Silica Powder, N. A. Shishacow 514; Patterns, 'Extra' Rings in, Dr. G. I. Finch and A. G. Quarrell, 720; Rings, 'Extra', Dr. L. H. Germer; Dr. G. I. Finch, 831
Electronic Charge, Viscosity of Air and the, Dr. G. Kellström, 682
Electrons in the Ionosphere, Frequency of Collisions of, T. L. Eckersley, 953
Elements, Artificial Transmutation of, Chemical Detection of, Prof. F. A. Paneth and H. Loleit, 950
Enzyme: Catalysis of the Exchange of Deuterium with Water, G. H. Bottomley, Dr. B. Cavanagh and Prof. M. Polanyi, 103; Action, Kinetics of Heterogeneous Catalysis and of, Prof. E. C. C. Baly, 146; Reaction, Spectroscopy of an, Dr. K. G. Stern, 335

Ergot, A New Alkaloid of, Dr. S. Smith and G. M. Timmis, 259
Erythema, Perspiration and, Prof. W. H. Crew, 340
Ethyl, Dipole Moments of, and *Iso*-amyl Borates and Triphenyl Phosphate, E. G. Cowley and Prof. J. R. Partington, 643
Eucalyptus Trees, Flies and Nematodes in Galls of, Symbiotic Association Between, G. A. Currie, 263
Eye, Induction of the, by a Specific Substance in the Amphibia, G. Lopashov, 835
Factor Analysis, Technique of, W. Stephenson, 297
Female Periurethral Glands and the Prostate, Homology of the, Dr. V. Korenchevsky, 185
Fermi's Theory, Production of Neutrons by Annihilation of Protons and Electrons According to, Dr. F. Bloch and Dr. C. Møller, 987
Field Theory, Quantised, and the Mass of the Proton, Dr. Max Born, 952
Fluorescence of Dyestuffs, Photochemical Reactions Connected with the Quenching of, by Ferrous Ions in Solution, Dr. J. Weiss, 794
Fluorine and Calcium, Induced Radioactivity of, Dr. O. R. Frisch, 220
Flying Fishes, Dr. E. L. Gill, 478
Follicular (Œstrus) Hormone and Plant Tumours, L. Havas, 516
Food and the Nation, Sir Herbert Maxwell, Bt., 956
Fossil Human Occipital Bone from Thames Gravels, K. P. Oakley and Dr. L. S. B. Leakey, 916
Fourier Analysis Applied to Vowel Vibrations, Failure of, Prof. E. W. Scripture, 223
Galapagos Islands, Charles Darwin and the, Mrs. Nora Barlow, 391
Gamma Rays, Neutrons and, Chemical Action caused by, and the Effects of these Agents on Colloids, Prof. F. L. Hopwood and J. T. Phillips, 1026
Gammarus : chevreuxi, Fertilisation of Successive Broods of, Mrs. E. W. Sexton, 477 ; Persistence of Sperms to a Later Mating in, K. W. Yarnold, 758 ; *chevreuxi*, Sexton, First Appearance of Red-eye in the Wild, Mrs. E. W. Sexton, A. R. Clark and G. M. Spooner, 836
Gaseous Organic Compounds, Certain, Thermal Decomposition of, Prof. M. W. Travers, 909
Glycogens, Fish and Rabbit Liver, Dr. D. J. Bell, 184
Glyoxalase Activation, Mechanism of, by Glutathione, J. Giršavičius and P. A. Heyfetz, 645
Gold : Palladium and, Isotopic Constitution of, Prof. A. J. Dempster, 65 ; Isotopic Constitution of, from Band-Spectroscopic Examination, Dr. S. Imanishi, 476
Gorilla Skulls in the Bristol Museum, H. Tetley, 642
Grass and Butter Carotenes, Adsorption of, on Alumina, A. E. Gillam and M. S. El Ridi, 914
Grasshopper, Locust and, Outbreaks, Rainfall-Evaporation Ratio in Relation to, Dr. J. Davidson, 298
Guanine in the Excreta of Arachnids, K. Vajropala, 145
Harmonic Oscillator, Uncertainty Principle and the Zero-Point Energy of the, R. A. Newing, 395
Heavy Water : Surface Tension of, H. Lachs and I. Minkow, 186 ; Supersaturated Vapour of, Formation of Drops in, Dr. L. Tronstad and H. Flood, 476 ; Density of 100 Per Cent, Dr. L. Tronstad, J. Nordhagen and J. Brun, 515 ; Raman Spectrum of, R. Anantha-krishnan, 551 ; Diffusion of, into Ordinary Water, M. Temkin, 552
Helium : 3 in Quantity, Attempts to Produce, Prof. F. A. Paneth and Prof. G. P. Thomson, 334 ; Content of the Stratosphere, Prof. F. A. Paneth and E. Glückauf, 717
Herbarium Material, Biometrical Studies on, Dr. E. Anderson and Dr. W. B. Turrill, 986
Heterogonic Growth, A Useful Application of the Principle of, A. E. Needham, 433
Hexadeuterobenzene : Vapour Pressure of, Dr. C. L. Wilson, 301 ; Infra-Red Spectrum of, and the Structure of Benzene, Dr. W. R. Angus, C. R. Bailey, Prof. C. K. Ingold, A. H. Leckie, C. G. Raisin, J. W. Thompson and Dr. C. L. Wilson, 680
High-Frequency Discharge, Initiation of the, Dr. J. Thomson, 300
Homologous Loci and Chromosome Conjugation, Dr. B. N. Sidorov, N. N. Sokolov and I. E. Trofimov, 108
Hooke, Robert, and his Contemporaries, T. E. James ; Dr. R. T. Gunther ; Prof. E. N. da C. Andrade, 603
Hydrogen in the Upper Atmosphere, Prof. J. Kaplan, 549
Hymenomycetes, Sexual Fusion in, Cytological Significance of the Nature of, Prof. S. R. Bose, 873
Insulin Inhibiting Agency in the Duodenum, An, Prof. A. B. Macallum, 32
Inverse Probability, Dr. T. E. Sterne ; Dr. H. Dingle, 301
Ionosphere, Electrons in the, Frequency of Collisions of, T. L. Eckersley, 953
Iridium : Isotopes and their Nuclear Spin, B. Venkatesachar and L. Sibaiya, 437 ; Isotopic Structure of, Prof. A. J. Dempster, 909
Iron Transition, Cinematographic Record of the $\alpha \rightleftarrows \gamma$, as Seen by the Electron-Microscope, Dr. W. G. Burgers and J. J. A. Ploos van Amstel, 721
Isotropic Transparent Solids, Measurement of the Elastic Constant of, Dr. E. Hiedemann, 337
Jensen Rat Sarcoma, Influence of Certain Polycyclic Hydrocarbons on the Growth of the, A. Haddow, 868
Kelvin and the Age of the Sun, C. Turnbull, 761
Kelvin's 'As if' in Physics, Prof. W. Peddie, 955
Kieselguhr, Adsorption of Aluminium Hydroxide by, Prof. E. C. C. Baly and W. P. Pepper, 28
Lecithin as a Dispersing Agent for Dibenzanthracene, H. D. Barnes, 756
Lightning Stroke, Return, Intensity Variations in the Channel of the, D. J. Malan, Dr. B. F. J. Schonland and H. Collens, 831
Line Standards, Precision of, A. Pérard, 104 ; Dr. W. E. Williams, 105
Liquid Dielectrics, Cosmic Ray Bursts in, Prof. C. Białobrzeski and I. Adamczewski, 109
Locust and Grasshopper Outbreaks, Rainfall-Evaporation Ratio in Relation to, Dr. J. Davidson, 298
Loris in Captivity, Breeding of, Prof. W. C. O. Hill, 107
Lumbricus, Oogenesis of, Cytoplasmic Bodies in the, Miss Gertrude Norminton and Prof. J. B. Gatenby, 916
Lung-fish, South American, Breeding in Captivity of the, C. W. Parsons, 954
Magnesium : Oxide, Crystalline, Properties of, Prof. R. W. Ditchburn and J. Harding, 70 ; And Sodium, *K*-Series of, Dr. V. Kunzl, 437
Magnetic : Susceptibility of Metals, Change of, During Melting and Allotropic Transformation, Prof. K. Honda and Y. Shimizu, 393 ; Storms and Upper-Atmospheric Ionisation, Prof. E. V. Appleton and Miss L. J. Ingram, 548
Man Again ? Origin of, W. W. L., 106
Management, The Profession of, W. R. Dunlop, 340
Mechanical Stresses at Higher Frequencies, New Methods for Measuring, Dr. A. Bloch, 223
Mercury Isotopes, Separation of the, by a Photochemical Method, Dr. K. Zuber, 796
Metaphysics of the Physical World, Prof. V. F. Lenzen, 433
Meteor Trail, Bright, Photographs of, of March 24, 1935, Dr. W. Bleeker, 224
Meteorites, Falling, Records of Fatalities from, M. A. R. Khan ; the Writer of the Review, 607 ; Dr. A. M. Heron, 1030
Methane, Oxidation of, Initial Formation of Methyl Alcohol in the, Prof. W. A. Bone, 910
Methyl : Iodide, Absorption Spectrum of, N. S. Bayliss, 264 ; Alcohol in the Oxidation of Methane, Initial Formation of, Prof. W. A. Bone, 910
Methylene Blue as a Stain for Mucus, A. G. Lowndes, 398
Microscope Technique, Prof. J. B. Gatenby, 723
Minkowski, Back to, Dr. F. W. Lanchester ; H. T. H. P., 760
Molecular Orientation and the Probability of Dissociation of Molecules by Electron Impact, Prof. N. Sasaki and T. Nakao, 260
Molecules, Probability of Dissociation of, Molecular Orientation and the, by Electron Impact, Prof. N. Sasaki and T. Nakao, 260

Morse's Rule, Suggested Improvements of, C. H. Douglas Clark and J. L. Stoves, 682
Music, Alchemy and, Prof. J. R. Partington; Prof. J. Read, 107
Myosin, Expansion of Films of, on Potassium Lactate, S. A. Moss, Jr., Prof. E. K. Rideal and E. C. Bate Smith, 260
NH, The Band Spectrum of, R. W. Lunt, Dr. R. W. B. Pearse and E. C. W. Smith, 32
NO_2 Molecule, Shape of the, Dr. G. B. B. M. Sutherland and Dr. W. G. Penney, 146
Nematodes in the Small Intestine of the Sheep, Distribution of, J. H. Tetley, 477
Neutron Bombardment, Radioactivity of Some Rare Earths Induced by, late Sir John C. McLennan and W. H. Rann, 831
Neutrons: Slow: Selective Absorption of, J. R. Tillman and Dr. P. B. Moon, 66; Prof. P. Lukirsky and T. Zarewa, 681; Excitation of Nuclei by, W. Ehrenberg, 870; Slow, Influence of the Velocity of, on their Capture by Certain Nuclei, Dr. P. Preiswerk and Dr. H. von Halban, Jr., 1027; Residual, Absorption of, Dr. L. Szilard, 950; the Slowing Down of, by Collisions with Protons, Dr. H. von Halban, Jr. and Dr. P. Preiswerk, 951; Production of, by Annihilation of Protons and Electrons according to Fermi's Theory, Dr. F. Bloch and Dr. C. Møller, 987; and Gamma Rays, Chemical Action caused by, and the Effects of these Agents on Colloids, Prof. F. L. Hopwood and J. T. Phillips, 1026
New Zealand Marlin Swordfishes, Presence of Roes in, V. W. Lindauer, 797
Nickel and Cobalt, Induced Radioactivity of, J. Rotblat, 515
Nitrogenous Substances, Structure and Oxidation of, Dr. C. N. Acharya, 644
Nitrous Oxide, Photodissociation of, Prof. P. K. Sen-Gupta, 513
Non-Cellulosic Constituents from Vegetable Fibres, X-Ray Examination of the Effect of Removing, W. T. Astbury, Dr. R. D. Preston and Dr. A. G. Norman, 391
Nova Herculis: and Cosmic Rays, Dr. A. K. Das, 29; Diurnal Variation of Cosmic Ray Intensity and, Dr. J. Barnóthy and Dr. M. Forró, 680
Nuclei, Excitation of, by Neutrons, W. Ehrenberg, 870
Nuclear Stability, Beta Processes and, Prof. G. Beck, 257
Oak, Sisal, Coir and, Molecular Structure in, Dr. E. N. M. Thomas and J. Hewitt, 69
Odontosyllis phosphorea, Moore, Swarming of, and of other Polychæta near Nanaimo, B.C., E. Berkeley, 1029
Œstrogenetic Substances, Chemistry of, E. Friedmann, 108; Prof. J. W. Cook, Prof. E. C. Dodds and F. L. Warren, 912
Optical Paths, Stationary, Dr. D. S. Kothari, 33
Organic Soils and Epinastic Response, Prof. W. Neilson Jones, 554
Ornithorhynchus, Dentition of, Dr. R. Broom, 219
Oxide: Film of Alloys Containing Small Percentages of Aluminium, I. Iitaka and S. Miyake, 437; Nitrous, Photodissociation of, Prof. P. K. Sen-Gupta, 513
Oxygen: in the Sun's Chromosphere, T. Royds, 606; Solid, Structure of, Prof. L. Vegard, 720; Isotopes, Electrolytic Separation of the, G. Ogden, 912
Ozone, Thermal Decomposition of, Dr. M. Ritchie, 221
Pacific, Surface Structure Beneath the, H. F. Baird, 723; Dr. R. Stoneley, 990
Palladium and Gold, Isotopic Constitution of, Prof. A. J. Dempster, 65
Para-Azoxyanisol, Viscosity of, Influence of a Magnetic Field on the, M. Miesowicz, 261
Parexocœtus, a Red Sea Flying Fish in the Mediterranean A. F. Bruun, 553
Perspiration and Erythema, Prof. W. H. Crew, 340
Philosophy and Modern Science, Dr. H. Jeffreys; Prof. H. Levy, 106; Prof. G. Dawes Hicks, 183; Dr. H. Jeffreys, 261
Phonemes, Prof. E. W. Scripture, 261; W. F. Twaddell; Prof. E. W. Scripture, 644
Phloridzin, Inhibitory Effect of, on an Enzymic Dismutation, H. Kalckar, 872
Phonetics, Experimental, and Ancient Greek Verse, Prof. E. W. Scripture, 340
Phosphorus Metabolism in Rats, Radioactive Indicators in the Study of, O. Chiewitz and Prof. G. Hevesy, 754
Photochemical Reactions Connected with the Quenching of Fluorescence of Dyestuffs by Ferrous Ions in Solution, Dr. J. Weiss, 794
Photosynthesis, the Rate of, Dr. W. O. James, 220
Physical: Reality, Quantum Mechanics and, Prof. N. Bohr, 65; Units and Their Dimensions, Sir Joseph Larmor, 548
Phytocarcinomata, Ascorbic Acid (Vitamin C) and, L. Havas, 989
Plankton Production and the Nitrate Nitrogen and Phosphate Cycles in the Pacific Ocean off New South Wales, Prof. W. J. Dakin and A. N. Colefax, 339
Plant: Virus Infection, the Problem of a, Dr. K. M. Smith, 395; Metabolism, Zinc and, Prof. W. Neilson Jones, 646; Lipochrome, a New Type of, Prof. I. M. Heilbron, B. Lythgoe and R. F. Phipers, 989
Plastic Bodies, Rupture of, Influence of Viscosity Variation on the, Dr. R. K. Schofield and G. W. S. Blair, 147
Platinum Isotopes and their Nuclear Spin, Prof. B. Venkatesachar and L. Sibaiya, 65
Pleochroism of Crystals of Rare-Earth Salts as Evidence of the Non-rotation of Certain Electronic Orbits, Dr. E. E. Jelley, 335
Podogona (Ricinulei), Rarity of the Archaic Arachnids, Dr. Susan Finnegan, 186
Positrons: from a Thorium-Active Deposit, Emission of, Prof. A. I. Alichanow, A. I. Alichanian and M. S. Kosodaew, 475; from Radioactive Sources, Emission of, Prof. A. I. Alichanow, A. I. Alichanian and M. S. Kosodaew, 719
Potassium: Lactate, Expansion of Films of Myosin on, S. A. Moss, Jr., Prof. E. K. Rideal and E. C. Bate Smith, 260; Radioactivity of, Dr. K. Sitte, 334; Iodide, Antagonistic Effect of, in Baldness due to Thallium Acetate, O. V. Hykeš and F. A. Diakov, 685; $_{19}K^{43}$ and the Radioactivity of, H. J. Walke, 755
Pre-Medical Studies, the Schools and, Dr. G. R. de Beer; W. J. R. D., 874
Probability, the Meaning of, W. Barrett; T. Smith; Dr. H. Dingle, 604
n-Propyl Radical, the Free, Dr. T. G. Pearson and Dr. R. H. Purcell, 221
Prosthetic Group of Catalase, Constitution of the, Dr. K. G. Stern, 302
Proton, Mass of the, Quantised Field Theory and the, Dr. Max Born, 952
Quantum: Mechanics and Physical Reality, Prof. N. Bohr, 65; Theory, the Fundamental Paradox of the, H. Fröhlich and E. Guth; Prof. G. Temple, 179; Dr. R. Peierls, 395
p-Quinone and Related Compounds, Electrical Moments of, D. Ll. Hammick, G. C. Hampson and G. I. Jenkins, 990
Rabbits, Rickets in, Incidence of, W. K. Wilson, 434
Radioactive: Elements, Artificially Produced, Beta-Ray Spectra of, Prof. A. I. Alichanow, A. I. Alichanian and B. S. Dželepow, 257; Indicators in the Study of Phosphorus Metabolism in Rats, O. Chiewitz and Prof. G. Hevesy, 754
Radioactivity: Artificial: of the Rare Earth Elements, Dr. J. K. Marsh and Prof. S. Sugden, 102; of Dysprosium and other Rare Earth Elements, Prof. G. Hevesy and Miss Hilde Levi, 103; of Potassium, Dr. K. Sitte, 334; Induced, by Bombarding Magnesium with α-Particles, Dr. C. D. Ellis and W. J. Henderson, 755; of Potassium, $_{19}K^{43}$ and the, H. J. Walke, 755; of Some Rare Earths Induced by Neutron Bombardment, late Sir John C. McLennan and W. H. Rann, 831; of Ferro-Manganese Formations in Seas and Lakes of the U.S.S.R., L. M. Kurbatov, 871; of Oil-Waters in Czechoslovakia, Prof. F. Běhounek, V. Santholzer and Prof. F. Ulrich, 910

Radio-Elements, Artificial, Deposition of, by Electrochemical Exchange, M. Haïssinsky, 141
Raman: Effect in Solutions of Some Amino Acids, N. Wright and W. C. Lee, 300; Spectrum of Heavy Water, R. Ananthakrishnan, 551
(*Ranzania*), the Oblong Sunfish, in the Indian Ocean, G. P. Whitley, 338
Rare Earth Elements: Artificial Radioactivity of the, Dr. J. K. Marsh and Prof. S. Sugden, 102; Dysprosium and other, Artificial Radioactivity of, Prof. G. Hevesy and Miss Hilde Levi, 103
Rat, Male, Sexual Organs of the, Activity of Androstendione on the, Dr. E. Tschopp, 258
Rayleigh Line in Liquids, Origin of the Wing Accompanying the, Dr. S. C. Sirkar, 759
Recession, Law of, Spiral Orbits and the, Dr. V. V. Narlikar and K. V. Sastry, 515
Recrystallisation Accompanying an Allotropic Change, Dr. C. F. Elam, 917
Red Clover, Development of, Effect of Pressure of Atmosphere on, Prof. P. W. Wilson, 262
Resorcinol, a Molecular Map of, Dr. J. M. Robertson, 755
Retina, the Metabolism of, Dr. H. Laser, 184
Rickets in Rabbits, Incidence of, W. K. Wilson, 434
Ring Deposits on Glass by Positive Ray Bombardment, Prof. B. Dasannacharya, V. T. Chiplonkar and L. G. Sapre, 642
Roes in New Zealand Marlin Swordfishes, Presence of, V. W. Lindauer, 797
Rubber, a Toxic Emanation from, Dr. K. Mellanby and Dr. P. A. Buxton, 873
Rusting Iron, the Electric Currents Flowing Over, Dr. U. R. Evans, 792
Salivary Gland, the Chromosome Micelle and the Banded Structure of Chromosomes in the, Dr. Dorothy M. Wrinch, 68
Samarium, Radioactivity of, Prof. H. J. Taylor, 719
Schardinger Enzyme Preparations, Oxidative Inactivation of Co-zymase with, Dr. F. Lipmann, 913
Schools, the, and Pre-Medical Studies, the, Dr. G. R. de Beer; W. J. R. D., 874
Science, Modern, Philosophy and, Dr. H. Jeffreys; Prof. H. Levy, 106; Prof. G. Dawes Hicks, 183; Dr. H. Jeffreys, 261
Scientific Publication be Controlled? Should, Prof. T. D. A. Cockerell, 222
SeO and SeO_2, Spectra of, Dr. R. K. Asundi, M. Jan-Khan and Prof. R. Samuel, 642
Seralbumins, Crystallisation of, Prof. R. Wernicke, 30
Sex Hormone Group, Synthesis in the, Dr. A. Cohen, 869
Sexual Fusion in Hymenomycetes, Cytological Significance of the Nature of, Prof. S. R. Bose, 873
Sisal, Coir and Oak, Molecular Structure in, Dr. E. N. M. Thomas and J. Hewitt, 69
Skeletal Movement, a New Type of, Dr. W. K. Spencer, 679
'Slow Neutrons', Velocity of, Dr. O. R. Frisch and E. T. Sørensen, 258
Social Science Investigation, A. Blair, 607
Sodium, Magnesium and, *K*-Series of, Dr. V. Kunzl, 437
Solutes, Molecular Polarisation of, and Dielectric Constant of, Solvents, Dr. R. J. W. Le Fèvre, 181
Solutions in an Electric Field, Optical Rotatory Power of, Prof. J. Kunz and A. McLean, 795
Solvents, Dielectric Constant of, Molecular Polarisation of Solutes and, Dr. R. J. W. Le Fèvre, 181
Sommerfeld's Theory of Ground Absorption, Negative Attenuation of Electromagnetic Waves and, Dr. S. R. Khastgir, D. N. Chandhuri and B. Sen-Gupta, 605
South: African Bullfrog, Carotid Gland of the, Dr. G. Eloff, 108; and East African Stone Age Typology, T. P. O'Brien, 475; 760; and East Africa, Archæology in, Prof. T. F. Dreyer, 872
Spark Counters of the Greinacher Type, a Simple Relay for, Dr. H. Teichmann, 871
Species Problem, The, K. Fœgri, 954
Spectra of SeO and SeO_2, Dr. R. K. Asundi, M. Jan-Khan and Prof. R. Samuel, 642
Spectrum Analysis, F. Twyman, 609; Dr. H. Dingle, 684
Speech Sounds, Overlapping of, Prof. E. W. Scripture, 759
Spiral Orbits and the Law of Recession, Dr. V. V. Narlikar and K. V. Sastry, 515
Statistical Tests, H. J. Buchanan-Wollaston, 182; Prof. Karl Pearson, 296; Prof. R. A. Fisher, 474; Prof. Karl Pearson, 550; H. J. Buchanan-Wollaston, 722; Prof. E. S. Pearson, 833
Stereoscopic Photography, J. van Zuylen; Dr. J. R. Baker, 551
Sterols, Acetylcholine and, in Tissues, Interaction between, Dr. G. S. Carter and Dr. L. W. Mapson, 143
Stone Age Typology, South and East African, T. P. O'Brien, 475, 760
Strainers, Prevention of Clogging of, in Rearing Aquatic Organisms, Dr. Ll. Lloyd, 646
Stratosphere: Helium Content of the, Prof. F. A. Paneth and E. Glückauf, 717; Threefold Coincidences in the, Vertical Intensity of Cosmic Rays by, Prof. E. Regener and G. Protzer, 718
Substituents, Influence of, on Organic Reactions: A Quantitative Relationship, Dr. G. N. Burkhardt, 684
Sulphuryl Diamide (Sulphamide), Reactions of, Dr. F. C. Wood, 837
Sun, Age of the, Kelvin and the, C. Turnbull, 761
Sun's Chromosphere, Oxygen in the, T. Royds, 606
Supra-Conducting State, Thermo-Electric Effect and the, Prof. E. F. Burton, F. G. A. Tarr and J. O. Wilhelm, 141
Symbols, Units and, Prof. A. V. Hill, 222
Tautomeric Selenazoles, Absorption Spectra of, Prof. R. F. Hunter, 1030
Tektites, Origin of, F. Watson, Jr., 105
Thallium Single Crystals, Diamagnetism of, Prof. S. R. Rao and K. C. Subramaniam, 336
Thames Gravels, Fossil Human Occipital Bone from, K. P. Oakley and Dr. L. S. B. Leakey, 916
Thermo-Electric Effect and the Supra-Conducting State, Prof. E. F. Burton, F. G. A. Tarr and J. O. Wilhelm, 141
Three-Carbon Tautomerism, Mechanism of, Dr. D. J. G. Ives and Dr. H. N. Rydon, 476
(*Trypanosoma equiperdum*) in Mammals, Effect of Low Temperature upon Trypanosomes, Dr. N. Kalabuchov and L. Levinson, 553
Units: and Symbols, Prof. A. V. Hill, 222; of Force in the M.K.S. System, Dr. L. Hartshorn and P. Vigoureux, 397
Universe, The Age of the, Sir James H. Jeans, 432: Dr. J. A. Chalmers and Bruce Chalmers, 916
University of London Council for Psychical Investigation", "The, Prof. A. V. Hill, 955
Upper: Carboniferous Fossils in America and Europe, Prof. T. D. A. Cockerell, 398; -Atmospheric Ionisation, Magnetic Storms and, Prof. E. V. Appleton and Miss Miss L. J. Ingram, 548; Atmosphere, Hydrogen in the, Prof. J. Kaplan, 549
Uranium, Isotopic Constitution of, Prof. A. J. Dempster, 180
U.S.S.R., Seas and Lakes of the, Radioactivity of Ferro-Manganese Formations in, L. M. Kurbatov, 871
Vegetable Fibres, X-Ray Examination of the Effect of Removing Non-Cellulosic Constituents from, J. Hewitt, 647
Ventilation and Domestic Heating, Sir Leonard Hill; The Writer of the Note, 225; Sir Leonard Hill, 339
Visual Purple System in Marine Fishes, the, G. Wald, 913
Vitamin: B, Plural Nature of, Prof. A. G. Hogan and L. R. Richardson, 186; B_1, A Crystalline Fluorescent Dehydrogenation Product from, Prof. G. Barger, F. Bergel and A. R. Todd, 259; C (Ascorbic Acid), Effect of, on the Growth of Plants: Dr. S. v. Hausen, 516; L. Havas, 646; in Lower Organisms, Dr. G. Bourne and R. Allen, 185; (Vitamin C and), Ascorbic Acid, Phytocarcinomata, L. Havas, 989; D, Natural Identity of, from Different Species of Animals, Dr. O. Rygh, 552; D_2 (Irradiated Ergosterol, Calciferol), and the Natural Vitamin D from Cod Liver Oil, Non-identity of, Dr. O. Rygh, 396

Vorticella, Swarming of, Prof. H. Munro Fox and H. G. Newth, 435
Vowel Vibrations, Failure of Fourier Analysis Applied to, Prof. E. W. Scripture, 223
Vowels, Puff and Profile Theory of the, Prof. E. W. Scripture, 435
War, Mathematical Psychology of, Dr. L. F. Richardson, 1025
Wax, a 'Dope' for Embedding, C. H. Waddington and J. Kriebel, 685
Whale, Blue, Endocrine Organs of the, A. P. Jacobsen, 1029
Wireless Waves, Negative Attenuation of, J. A. Ratcliffe and F. W. G. White, 794
Wood Hemicelluloses, W. G. Campbell, 299
X-Ray Powder Patterns, New Technique for Obtaining, R. A. Stephen and R. J. Barnes, 793; Reflections from Microcrystalline Layers, Conditions Determining the Intensity of, Dr. J. Brentano, 988
X-Rays: and Electrons, Diffraction of, by Carbon Tetrachloride Vapour, C. Degard, J. Piérard and Dr. W. van der Grinten, 142; Polarised, Intensity of, Dr. W. H. George, 180; Short Wave-length, Absorption of, Dr. W. V. Mayneord and J. E. Roberts, 793; Long Wave-lengths of, Occurrence of the Reversed Absorption Edges of the, M. Bačkovský and Prof. V. Dolejšek, 836
Zinc: and Plant Metabolism, Prof. W. Neilson Jones, 646; Oxide, Variation in the Lattice Constant of, V. E. Cosslett, 988

Corrosion of Iron by Acids, Substances Inhibiting the, J. Bancelin and Y. Crimail, 1038
Cortina d'Ampezzo und Cadore, Geologie von, Dr. Maria M. Ogilvie Gordon (*Review*), 48
Cosmic: Rays, Nova Herculis and, Dr. A. K. Das, 29; Ray Bursts in Liquid Dielectrics, Prof. C. Białobrzeski and I. Adamczewski, 109; Rays, Equatorial Longitude Effects on, Prof. R. A. Millikan and H. V. Neher, 407. Ray Intensity, Diurnal Variation of, and Nova Herculis, Dr. J. Barnóthy and Dr. M. Forró, 680; Radiation, Primary, Positive and Negative Ions in the, H. J. Walke, 681; Rays, Vertical Intensity of, by Threefold Coincidences in the Stratosphere, Prof. E. Regener and G. Pfotzer, 718; Ray Showers, Production of, at a Considerable Depth Below Ground-level, D. H. Follett and J. D. Crawshaw, 1026
Cotswold Long Barrow, 365
Coward, T. A., memorial sanctuaries, 174
Cowpea Rust, Dr. T. Fahmy, 343
Crab Glycolysis, Chemistry of, R. Willheim and Charlotte Frisch (1), 235
Crabs, New Pinnotherid, T. Sakai; S. A. Glassell, 305
Cracked Spirit in Internal Combustion Motors, Use of, E. Vellinger and G. Radulesco, 81
Crane Hooks and Other Components in Lifting Gear, Design of, Gough, Cox and Sopwith, 401
Crete: Archæological Discovery in, Dr. Marinatos, 15; Recent Archæological Discoveries in, Sir Arthur Evans, 175; Later, Minoan Survivals in, Sir Arthur Evans, 903
Cricket-Bat Willow, Watermark Disease of the, Dr. W. J. Dowson, 610
Crop Varieties and Related Species, Collection and Classification of, Prof. E. E. Cheesman, 404
Cross, Dorothy Temple, Fellowships of the Medical Research Council, awards made to, Dr. G. B. Brook, Dr. J. W. Craig and A. H. B. Rhodes, 218
Crossing-Over and Chromosome Disjunction, Dr. S. Gershenson, 834; Dr. C. D. Darlington, 835
Crystal: Grown by the Bridgman Method, Sub-Boundaries in a, Dr. W. H. George, 392; Structure, a Study of, and its Applications, Prof. W. P. Davey; Dr. R. E. Gibbs (*Review*), 528
Crystalline Suspensions, Deposition of, G. Bezza (1), 731
Crystals: Ideal and Real (*Review*), 165; Anomalous Specific Heats of, Prof. R. H. Fowler (Bakerian lecture), 726; Elastic Constants of, New Optical Method for the Determination of the, C. Schaefer and L. Bergmann, 731; Infra-Red Absorption of, R. B. Barnes, R. R. Brattain and F. Seitz, 994
Ctenoplana, Structure of, Dr. T. Komai, 1032
Cuban Society of Biology, Prof. W. H. Hoffmann elected president of the, 908
'*Culex pipiens*' (Diptera, Culicidæ), 'Autogenous' Strains of, J. F. Marshall and J. Staley, 641
Culture, Patterns of, Dr. Ruth Benedict (*Review*), 322
Cultures: Primitive, the Dream in, Dr. J. S. Lincoln (*Review*), 969; The Blending of, an Essay on the Aims of Native Education, F. C. Williams, 1019
Cupric Compounds, Structure of, E. G. Cox and K. C. Webster, 112
Cuprous Oxide, Internal and Superficial Conductivity of, L. Dubar, 964
Current-Measuring Apparatus, New, Dr. J. N. Carruthers, 1032
Current Science, 468
Cuvier, Unveiling of Statue of, [1835], 272
Cyclohexane Rings, Multiplanar, Prof. M. Qudrat-i-Khuda, 301; Dr. R. D. Desai and Prof. R. F. Hunter, 608; 953
Cytologie, Grundriss der, Dr. L. Geitler (*Review*), 495
Czechoslovakia, Radioactivity of Oil-Waters in, Prof. F. Běhounek, V. Santholzer and Prof. F. Ulrich, 910

Daffodils, Stripe Disease of, N. K. Gould, 1032
Dairy Cow, Lability of the Basal Metabolism of the, F. G. Benedict and E. G. Ritzman, 407
Darwin: in Peru [1835], 80; and the Galapagos Islands, Mrs. Nora Barlow, 391; in the Galapagos Archipelago [1835], 448; and H.M.S. *Beagle*, 506; Visit to the Galapagos Archipelago, Centenary of, 506; Sir Edward Poulton and others, 534; at Tahiti, [1835], 768; as a student in Edinburgh, 1825–27, Prof. J. H. Ashworth, 1011
Darwiniana for Down House, 862
Datura, Pollen-tube Growth of a Translocation of the 1·2 Chromosome in, J. T. Buchholz, A. F. Blakeslee and A. G. Avery, 120
Deafness, Experimental, A. F. Rawdon-Smith, 32
De Bilt, Seismological Station of, Report of Earthquakes in 1932, 217
Decapod Crustacea, Probable Connexion between the Blood Gland and the Chromatophore Activator in, B. Hanström, 925
De Donder's, Th., Thermodynamic Synthesis Applied to the Transverse Nernst and Ettingshausen Effects, Yvonne Dupont (3), 655
Dee, River (Aberdeenshire) Flow Records, 544
Deep Sea Mud, Celluloid Tubes for Sampling Cores of, N. J. Tarasov, 263
Dementia nomenclatorica americana, E. Heron-Allen, 797
Denmark's, King of, Medal for Astronomers, [1835], 731
Dental Caries in Prehistoric South Africans, Prof. T. F. Dreyer, 302
Dent du Midi, Fall of the, [1835], 310
Depigmentation, a New Dietary Deficiency Disease, Cured by Copper, Dr. F. J. Gorter, 185
Desert: Man Conquers the, Prof. V. Gordon Childe (*Review*), 353; Plants, Transpiration and Stomata in, A. H. Nontasir and A. M. Nigaleid, 993
Detonation: Spectra, Variation of, with the Nature of the Surrounding Gas, A. Michel-Lévy and A. Muraour, 924; Spin in, the Phenomena of, 974
Deuterium: with Water, Exchange of, Enzyme Catalysis of the, G. H. Bottomley, Dr. B. Cavanagh and Prof. M. Polanyi, 103; into Metals, Diffusibility of, T. Franzini, 564; Continuous Spectrum of, Mlle. Arlette Tournaire and E. Vassy, 1002
Deuterons, Transmutation by, E. O. Lawrence, E. McMillan and R. L. Thornton, 839
Developmental Condition in a Boy, Rare, 138

Diamagnetic Susceptibilities, Effect of Light on, H. C. Bhuyan, 872
Diatomaceous Deposit of the Lower Barm Valley, Excavation of the, H. L. Movius, Jr., 80
Dibenzanthracene, Lecithin as a Dispensing Agent for, H. D. Barnes, 756
Dicotyledons, Vessel-less, K. M. Gupta, 400
Dielectric: Constant of Ionised Air, Prof. S. K. Mitra and S. S. Bannerjee, 512; Constants of Strong Electrolytes of Low Concentrations at Varying Temperatures, W. M. Jezewski, M. Wierzbicki and J. Kamecki, 526
Diesel: Engines and Coastal Shipping, Dr. S. J. Davies, 665; Engine Design, H. F. Shepherd (*Review*), 282; Motors, Detonation in, R. Retel, 525; Fuel Research, Prof. P. H. Schweitzer and T. B. Hetzel, 994
Diet, British Association Discussion on Economics of, 631
Dietary Hæmorrhagic Disease in Chicks, H. J. Almquist and E. L. R. Stokstad, 31
Differential: Equations, Numerical Studies in, Prof. H. Levy and E. A. Baggott. Vol. 1 (*Review*), 458; Calculus, The, T. Chaundy (*Review*), 595
Dioxane, D_2O, Ice and D_2O in, Extreme Infra-Red Absorption of, C. H. Cartwright, 181
Diphtheria Bacillus, Chemical Studies on the, M. A. Machebœuf and H. Cassagne, 119
Dipterocarpaceæ-Dipterocarpoideæ, Occurrence of the, in Africa, Dr. J. Burtt Davy, 991
Dipterous Insect, a Remarkable, M. Tokunaga, 762
Direction Finding and Blind Flying for Civil Aviation, 252
Discharge Tube Vapour Lamp, A New, 688
Discoveries: Old and New (*Review*), 701; the Accessibility of, Sir Joseph Larmor, 722
Discovery II: New Commission of the, 576; 1933–35, Dr. N. A. Mackintosh, 629
Divination in Melanesia, F. L. S. Bell, 72
Divine Kings in Southern Nigeria, M. W. D. Jeffreys, 480
Documentation: Dr. J. A. Prins and others, 727; International Institute of, Copenhagen Congress, 727
Dolomites, Eastern, Structure of the (*Review*), 48
Domestic Heating, Ventilation and, Sir Leonard Hill; The Writer of the Note, 225; 339
Dorset Coast, The, a Geological Guide, G. M. Davies (*Review*), 935
Dovedale, further gifts of parts of, by R. McDougall, 177
Dove Marine Laboratory, Report for Year ending July 31, 1934, 580
Dover, Straits of, The Flow of Water through the, Dr. J. N. Carruthers, 306
Downy Mildew of Italian Millet, Mycological and Pathological Studies on the, M. Hiura, 228
Dreams: On, W. Archer. Edited by T. Besterman (*Review*), 597; and Culture (*Review*), 969
Drosera capensis, L., Food Reception and Transport by the Leaves of, J. Oudman, 235
Drosophila: *melanogaster*, Structure of, E. H. Strasburger, 150; X-Ray and Abnormalities: Increased Abnormality of Segments in, due to X-Raying of Gametes, E. Lucile Smith, 408; X-Rayed, Determination of the Magnitude of the Cell 'Sensitive Volume' Associated with the White-eye Mutation in, C. P. Haskins, 925
Dublin University, Conferments of honorary degrees, 117
Duodenum, An Insulin Inhibiting Agency in the, Prof. A. B. Macallum, 32
Durham University, Commissioners of, 233
Dutch East Indies: Marine Fauna of the, 35; Crabs from the, Dr. Isabella Gordon, 648
Dynamic Universes Endowed with Complete Symmetry about a Centre, Typical Case of, C. Tolotti, 564
Dynamo-Electric Machine in its Historical Development: Documents and Materials. Collected by D. V. Efremov and M. I. Radovskij. Edited by V. T. Mitkevitch (*Review*), 778
Dyspnea, Clinical, Relation of the Regulatory Mechanism of Respiration to, W. R. Dickinson, Jr., A. Cournand and I. Rappaport, 488
Dysprosium and other Rare Earth Elements, Artificial Radioactivity of, Prof. G. Hevesy and Miss Hilde Levi, 103
Ear Exostoses, Dr. A. Hrdlička, 227
Early Stone Age Culture of America, An, 535
Earth: The Changeful, 351; Pressure on Flexible Walls, J. P. R. N. Stroyer, 866
Earthquake: in Lancashire [1835], 272; Quetta, of May 31, 331; Provincetown, Mass., of April 23, 1935, L. D. Leet, 407; Bihar, of 1934, J. B. Auden and A. M. N. Ghosh; N. Nasu, 485; Nevada, of 1934, E. Callaghan and V. P. Gianella, 649; Canadian, of Nov. 1, 753; Research Commission for India, 907
Earthquakes: Deep-focus, A New Wave Characteristic of, R. C. Hayes, 337; Formosa and Quetta, R. Takahasi, 441; Destructive, in 1934, C. Bois, 472; Recent, 510; in New Zealand, Distribution of, L. Bastings and R. C. Hayes, 519; Destructive, in 1935, C. Bois, 639; British and Irish, Investigation of, 907; Catalogue of, 1925-30, 907; Tokyo, in 1934, 919; and Rainfall, J. F. Brennan, 958
Earth's: Atmosphere, Circulation of the, 331; Crust, Horizontal Distortion of the, near Tokyo, C. Tsuboi, 993; Magnetic Field, Dr. R. A. Millikan, 982
East: Malling Research Station, Twenty-second Annual Report of the, 138; Anglia: Archæological Research and Peat Deposits in, J. G. D. Clark, Dr. H. and Mrs. M. E. Godwin and M. H. Clifford, 304; A Long Barrow in, 948; Africa: Ancient Ruins in, Dr. L. S. B. Leakey, 638; Black and White in, the Fabric of a New Civilization, Dr. R. C. Thurnwald. With a Chapter on Women, by Hilde Thurnwald (*Review*), 1004
Economic Nationalism and International Trade, Prof. J. G. Smith, 383
Edinburgh University: conferment of degrees, 41; Sir Charles Sherrington appointed Gifford lecturer for 1936-37 and 1937-38; conferment of an honorary doctorate on Prof. A. N. Richards, 155; grant by the Rockefeller Foundation, 768; proposed Walker memorial lecture, 827
Edingtonites, Substituted, X-Ray Study of, W. H. Taylor, 920
Education: Science of [1835], 42; A New Frontier in, 156; and Freedom, Dr. A. W. Pickard-Cambridge, 387; 416; and Leisure in Progressive Life, 847
Educational Films and 16mm. Apparatus, A National Encyclopædia of (*Review*), 1007
Eels: Schmidt and the, Danish Eel Investigations during twenty-five years, 820
Egg Case in the Crustacea, Origin and Nature of the, Prof. C. M. Yonge, 67
Egypt: Medical Research in, 430; Ancient, Weights and Balances in, Prof. S. R. K. Glanville, 788
Egyptian Plant Diseases, G. H. Jones, 509
Einstein, Albert, a Picture of His Life and His Conception of the World, Prof. D. Reichinstein (*Review*), 934
Einstein's: Gravitational Equations, Prof. J. Ghosh, 151; Eyes, Through (*Review*), 164
Elasmobranchs from Puget Sound, A. C. DeLacy and W. M. Chapman, 918
Elastic Solids in Practice, Theory of, R. Poole, 520
Electric: Arc, Structure of the, N. Szulc, 311; Generating Stations, Private, Closing down of, 578; Currents flowing over Rusting Iron, The, Dr. U. R. Evans, 792; Charge collected by Water-drops falling through a cloud of Electrically Charged Particles in a Vertical Electric Field, J. P. Gott, 806; Transients, Introduction to, Prof. B. Kurtz and Prof. G. F. Corcoran (*Review*), 892
Electrical: Units and the I.E.C., 15; Sir Richard T. Glazebrook, 71; 110; and General Engineering, Recent Developments in, M. G. S. Swallow, 130; Units and the I.E.C., Dr. N. R. Campbell, 148; Engineering, Problems in, with Answers, edited by Prof. S. Parker Smith. Second edition (*Review*), 594; Water Heating: with special reference to the Domestic Storage Heater, D. J. Bolton, P. C. Honey and N. S. Richardson (*Review*), 625; Measurements, Absolute Units and, Sir Richard Glazebrook, 667; Units, International and Absolute, 728; Supply Industry, The Socialization of the, G. H. (*Review*),

739 ; Conductance of Short Gaps in Air, E. Hutchisson, T. H. Osgood and R. E. Fearon, 769 ; Plant, Sale of Second-hand, Col. H. C. Fraser, 865
Electricity : Authority, London and Home Counties Joint, 750 ; in Poultry Farming, C. A. C. Brown (*Review*), 892
Electrolysis, Industrial Applications of, H. J. T. Ellingham, 839
Electrolytes, Colloidal : A General Discussion held by the Faraday Society (*Review*), 593
Electrolytic Conductivity of Extremely Dilute Solutions, Measurement of the, M. Hlasko and A. Salit, 158
Electromagnetic : Moments, L. Henriot, 81 ; Waves, Negative Attenuation of, and Sommerfeld's theory of Ground Absorption, Dr. S. R. Khastgir, D. N. Chandhuri and B. Sen Gupta, 605
Electron : Pairs, Production of, Prof. G. Racah, 393 ; Diffraction by Vitreous Silica Powder, N. A. Shishacow, 514 ; Emission and Adsorption Phenomena, Dr. J. H. de Boer. Translated from the manuscript of Mrs. H. E. Teves-Acly (*Review*), 589 ; Diffraction Patterns, 'Extra' Rings in, Dr. G. I. Finch and A. G. Quarrell, 720 ; Liberation of the, C. C. Paterson, 748 ; 'Extra', Diffraction Rings, Dr. L. H. Germer ; Dr. G. I. Finch, 832
Electronic Charge, Viscosity of Air and the, Dr. G. Kellström, 682
Electrons : (*Review*), 320 ; (+ and −), Protons, Photons, Neutrons and Cosmic Rays, Prof. R. A. Millikan (*Review*), 320 ; in the Ionosphere, Frequency of Collisions of, T. L. Eckersley, 953 ; Diffraction of, by Chloroform, and the Structure of the Molecule, C. Desard, 1001
Electrostatics : Faraday Borrows a Copper [1835], 882 ; a Cold Night on the Roof [1835], 924
Elements, Artificial Transmutation of, Chemical Detection of, Prof. F. A. Paneth and H. Loleit, 950
Elettrocustica del linguaggio, L'Analisi, A. Gemelli e G. Pastori. 1 : Testo ; 2 : Atlante della tavole (*Review*), 455
Ellesmere Island, Explorations in, 828
Elliptic Integrals, Complete and Incomplete, Tables of the, Legendre, with an Introduction by Prof. Karl Pearson (*Review*), 356
Emanation to Water flowing over Radium-containing Rocks, Output of, H. Mache and G. Markstein, 450
Embryology, Experimental, An Introduction to, Dr. G. R. de Beer. Second edition (*Review*), 702
Empire : Survey Officers, Conference of, 139 ; Meteorologists, Conference of, 404
Emulsions, Technical Aspects of (*Review*), 281
Emyda vittata, Digestive Tract of, A. Narayana Rao, 687
Endocrine Glands, The Diseases of the, Dr. H. Zondek. Third edition, translated by Dr. C. Prausnitz (*Review*), 355
Engineer and the Community, C. H. Bailey, 902
Engineering, Stability in, J. S. Wilson, 383
Engineers' Study Group on Economics, Sir Richard Gregory, Bt., elected president of the, 601
English, This, Sir Richard Paget, Bt. (*Review*), 596
Entomological : Society [1835], 195 ; 562 ; Conference, Imperial, Fourth, 652 ; Society, Meeting of the [1835], 730
Entomology, Sixth International Congress of, 728
Enzyme : Catalysis of the Exchange of Deuterium with Water, G. H. Bottomley, Dr. B. Cavanagh and Prof. M. Polanyi, 103 ; Action, Kinetics of Heterogeneous Catalysis and of, Prof. E. C. C. Baly, 146 ; Reaction, Spectroscopy of an, Dr. K. G. Stern, 335 ; Study, Progress in (*Review*), 624
Enzymforschung, Ergebnisse der, Herausgegeben von F. F. Nord und R. Weidenhagen. Band 4 (*Review*), 624
Eocene Foraminifera, J. A. Cushman, 344
Epidemics : Notable, and their causes, Sir William H. Hamer (*Review*), 47 ; Some Notable, Dr. H. H. Scott (*Review*), 47 ; and Crowd-Diseases : an Introduction to the Study of Epidemiology, Prof. Major Greenwood ; Dr. P. Stocks (*Review*), 700
Erdöl-Muttersubstanz : Beiträge zu dieser Frage, Dr. F. E. Hecht, and others (*Review*), 891
Ergometrine, Pharmacology of, G. L. Brown and Sir Henry Dale, 844
Ergot, A New Alkaloid of, Dr. S. Smith and G. M. Timmis, 259
Erinnerungen und Welteindrücke eines Naturforschers, Prof. H. Molisch (*Review*), 494
Erosion Surfaces, Dr. S. W. Wooldridge, 897
Erythema, Perspiration and, Prof. W. H. Crew, 340
Eskimo Migrations, Dr. T. Mathiassen, 188
Essays, Collected, Prof. F. H. Bradley. 2 Vols. (*Review*), 852
Ethyl and *Iso*-amyl Borates and Triphenyl Phosphate, Dipole Moments of, E. G. Cowley and Prof. J. R. Partington, 643
Eucalyptus : *Australiana*, Essential Oils of, and its Physiological Forms, A. R. Penfold and F. R. Morrison (1), 845 ; Trees, Galls of, Symbiotic Association between Flies and Nematodes in, G. A. Currie, 263
Eugenic Organizations, International Federation of, Eleventh Assembly of the, 368
Euplœa (*crastia*) *core asela*, Moore (Lepidoptera, Danainæ), The Epigamic Behaviour of, O. H. Latter and H. Eltringham, 42
Europe : a Regional Geography, Margaret Reid Shackleton (*Review*), 595
European : Aeronautical Society [1835], 79 ; Civilisation, The Oldest (*Review*), 202 ; Pre-history, Terminology in, A. J. H. Goodwin, 617
Europeans : We, a Survey of 'Racial' Problems, Dr. J. S. Huxley and Dr. A. C. Haddon. With a chapter on Europe overseas, by Prof. A. M. Carr-Saunders (*Review*), 736
Evaporation : Experiments in Vacuum with Polonium, Radium D and Radium E, Margarete Hoffer, 407 ; of Polonium in Oxygen and Nitrogen, Elisabeth Rona and Margarete Hoffer, 407
"Everyday Science" : and Civil Service Examinations, 825 ; and the Civil Service Commissioners, 984
Examinations, An Examination of, Sir Philip Hartog and Dr. E. C. Rhodes (*Review*), 966
Exhibition of 1851, Royal Commission for the, awards of studentships and scholarships for 1935, 79
Existence, The Struggle for, G. F. Gause (*Review*), 322
Exploded Wires, Spectra of, in the Extreme Ultra-Violet and the Schumann Region, G. Vaudet and R. Servant, 406
Explorer II : U.S. Stratosphere Balloon, Destruction of, 99 ; Record Ascent of, 786
Explosive Substances, Measurement of the Pressures developed by, P. Bernard, 43
Eye, Induction of the, by a Specific Substance in the Amphibia, G. Lopashov, 835

Factor Analysis, Technique of, W. Stephenson, 297
Factories and Workshops, Annual Report of the Chief Inspector of, for the Year 1934, 928
Faith and Fact, Rev. J. C. Hardwick (*Review*), 888
Family Meals and Catering, 691
Faraday : on Tour in Switzerland [1835], 80 ; and Lord Melbourne [1835], 923
Faraday's : Mistakes, One of [1835], 348 ; Eyesight and the Blind Spot, Dr. F. Marsh, 542 ; Researches on Electrostatics, Beginning of [1835], 730 ; Diary, Vol. 6 (*Review*), 739
Farm and Machine, Vol. 2, 138
Farming Shelterbelts, Dr. R. M. Gorrie, 510
Faune de France. 28 : Diptères (Brachycères), (Muscidae Acalypterae et Scatophagidae), E. Séguy (*Review*), 458
Fayum, The Desert, Miss G. Caton-Thompson and Miss E. W. Gardner (*Review*), 353
Female Periurethral Glands and the Prostate, Homology of the, Dr. V. Korenchevsky, 185
Fen Drainage Problems, Major R. G. Clark, 469
Fens, Excavations in the, 213

Fermi's Theory, Production of Neutrons by Annihilation of Protons and Electrons According to, Dr. F. Bloch and Dr. C. Møller, 987
Ferromagnetic Powders, Magnetisation at a High Temperature of, H. Forestier, 311
Field: Museum of Chicago, Annual Report for 1934, 217; Theory, Quantised, and the Mass of the Proton, Dr. Max Born, 952
Film in the School, the, Edited by J. A. Lauwerys (*Review*), 1007
Fire: and Burglar Alarms, Automatic, 946; Resistance of Buildings, 996
Firedamp, Ignition of, by Compression, late Prof. H. B. Dixon and J. Harwood, 482
Firewalking: Demonstration of, by Kuda Bux, 468; C. R. Darling, 521
Fish and the Ring, G. P. Whitley, 390
Fischer, Emil, medal, award of the, to Prof. A. Butenandt, 547
Five Years: The Next, an Essay in Political Agreement (*Review*), 735
Flahault, Prof. Charles, and the Scots College at Montpellier: Proposed memorial, 841
Flamsteed", "Account of, Baily's [1835], 525
Flight Experiments with Compression-Ignition Engines, 136
Floods, November, 826
Flow as a Property of Matter (*Review*), 697
Flower Book for the Pocket, A, Prof. Macgregor Skene (*Review*), 458
Flowers, The Biology of, W. O. James and A. R. Clapham (*Review*), 494
Fluorescence of Dyestuffs, Photochemical Reactions connected with the Quenching of, by Ferrous Ions in solution, Dr. J. Weiss, 794
Fluorine: and Calcium, Induced Radioactivity of, Dr. O. R. Frisch, 220; Poisoning of Plants by, Prof. A. Contardi and C. Ravazzoni, 266
Flying: Fishes, Dr. E. L. Gill, 478; Boats, New, for British Empire Air Lines, 577
Folk Dancing: Conference on, 59; International Conference on, 135, 154; Dr. Elise van der Ven Ten and others, 154
Follicular (Œstrus) Hormone and Plant Tumours, L. Havas, 516
Folsom Complex: A, Preliminary Report on Investigations at the Lindenmeier Site in Northern Colorado, F. H. H. Roberts, Jr., 535
Food: Investigation: Index to the Literature of, Agnes Elisabeth Glennie, assisted by O. Davies, 389; Progress of, 941; Poisoning, Memorandum on, 546; Farmer and Future, Prof. H. E. Armstrong, 565; Policy, National, 631; Supplies and Health, 657; and the Nation, 771; Sir Herbert Maxwell, Bt., 956; -Habit, Induced, Transference of, from Parent to Offspring, D. E. Sladden (2), 844; Aluminium in, Dr. G. W. Monier-Williams, 961
Foraminifera, The Economic Importance of the, Dr. H. Dighton Thomas, 130
Foraminiferal Limestone of Eocene Age from North-West Division, Western Australia, F. Chapman and Irene Crespin, 349
Forbes, Prof. J. D.: in the Pyrenees [1835], 42; 156; on the Puy de Dôme [1835], 486
Force, Lord Davies. Re-issue, 275
'Foreign' Words, New German renderings of, Dr. G. Joos, 675
Forest: Mice, Geographical Races in, Physiological differences between, Kalabuchov, 35; Tropical Rain, Three areas of, P. Richards, 403; Types in Nyasaland, P. Topham; W. D. MacGregor, 403; *Products Research Records*, Nos. 1 and 2, 905
Forestry: in Wales, Some Aspects of, H. A. Hydes, 293; Problems of, 331; Commission, Fifteenth Annual Report, 451
Forests, Teaching the Value of, 293
Formol in very Dilute Solutions, Estimation by Weight and the Identification by Elementary Analysis of small quantities of, R. Fosse, P. E. Thomas and P. de Graeve, 348
Fossil: Elephants in Eldorado, 546; Cephalopoda in the British Museum (Natural History), Catalogue of the, Part 4: the Ammonoidea of the Trias, Dr. L. F. Spath (*Review*), 778; Human Occipital Bone from Thames Gravels, K. P. Oakley and Dr. L. S. B. Leakey, 916
Fossiles: Les, éléments de paléontologie, Prof. M. Boule et Dr. J. Piveteau (*Review*), 1009
Fourier Analysis applied to Vowel Vibrations, Failure of, Prof. E. W. Scripture, 223
Fracastor's Poem on Syphilis (*Review*), 586
Fraternities, Tempo of the Growth of, F. Boas, 487
Fraunhofer Lines, Intensities of, Dr. C. W. Allen, 920
French Academy of Moral and Political Sciences, Prof. J. Lepine elected a member of the, 64
Fresnel, Submarine, a Gravimetric Cruise of the, in the North-west Part of the Mediterranean Basin in 1933-34, P. Marti, 1038
Friedelin, Cerin and, N. L. Drake and R. P. Jacobsen, 726
Frogs of the family Microhylidae, A Monograph of the, H. W. Parker (*Review*), 529
Frost, Early, in 1835 and 1935, Miss E. Armitage, 753
Fruit: Gas Storage of, 59; Growing, Award for research in, 63; Trees, Chlorosis of, A Cure for Lime-induced, Dr. T. Wallace, 111; Tropical, Storage of, Dr. C. Wardlaw and R. Leonard, 403; Maturity of, Dr. J. C. Hinton, 687; Trees, Growth records on, M. C. Vyvyan, 800; Deciduous, I. Donen (3), 807
Fuel: Research Institute of South Africa, Activities of the, Dr. J. G. Vogel, 255; Institute of, Melchett medal of the, H. R. Ricardo presented with the, 714 for Internal Combustion Engines, a Rational Scale of Classification of, M. Serruys, 924
Fuels, Liquid, H. Moore (*Review*), 598
Fundulus, Processes of Localisation in Developing, Jane M. Oppenheimer, 769
Fungi: Longevity of, Ö. Winge and A. Hjort, 305; High Temperature variations in, Dr. B. Barnes, 481; Polyporous, Secondary Spores of, S. R. Bose, 481

Gadolinium: G. Urbain, P. Weiss and F. Trombe, 234; Metallic, Paramagnetism of, above its Curie point, F. Trombe, 807
Galapagos: Islands, Charles Darwin and the, Mrs. Nora Barlow, 391; Fauna, Protection of the, 427; Islands, Centenary of the landing of Charles Darwin on the, Sir Edward Poulton and others, 534; Archipelago, Tortoises of the [1835], 562
Galileo and the Leaning Tower of Pisa, Dr. R. T. Gunther (*Review*), 6
'Galjoen' Fishes of South Africa, J. L. B. Smith, 157
Gallo-Roman Official in Early Britain, C. F. C. Hawkes, 1031
Game: Rearing, American Universities and, J. N. Darling, 522; Animals of the British Empire, Preservation of, 619
Gamma: Ray Energy Measurement, the Ionisation Method of, Dr. L. H. Gray, 960; Rays, Chemical Action Caused by Neutrons and, and the Effects of these Agents on Colloids, Prof. F. L. Hopwood and J. T. Phillips, 1026
Gammarus: *chevreuxi*: Fertilisation of Successive Broods of, Mrs. E. W. Sexton, 477; Sexton, First Appearance of Red-eye in the Wild, Mrs. E. W. Sexton, A. R. Clare and G. M. Spooner, 836; Persistence of Sperms to a Later Mating in, K. W. Yarnold, 758
Garden: the Living, or the How and Why of Garden Life, Prof. E. J. Salisbury (*Review*), 931
Gardening in East Africa. Edited by A. J. Jex-Blake (*Review*), 321
Garonne, River, Flood Regimen of the, Prof. M. Pardé, 993
Gas: or Electricity for Domestic Heating ?, Prof. W. A. Bone, 16; Poison, A. Marshall, 170; Defence, J. Davidson Pratt, 171; Industry, Progress in the, 742
Gasentladungstabellen: Tabellen, Formeln und Kurven zur Physik und Technik der Elektronen und Ionen, M. Knoll, F. Ollendorff und R. Rompe. Unter Mitarbeit von A. Roggendorf (*Review*), 356

Gaseous: Explosions, Flame Movement in, Prof. W. A. Bone, R. P. Fraser and W. H. Wheeler, 42; Exchanges of some Submerged Aquatic Plants in the Course of Assimilation, F. Gorski, 158; Organic Compounds, Certain, Thermal Decomposition of, Prof. M. W. Travers, 909
Gases: through Metals, Diffusion of, Dr. C. J. Smithells and C. E. Ransley, 36; contained in Metals, A New Method of Extracting the, L. Moreau, G. Chaudron and A. Portevin, 406; New Kinetic theory of, Dr. I. I. Rabi, 764; with Solids, The Interaction of, Dr. H. W. Melville, 899
Gasteria, Sensitive-volume of the Meiotic Chromonemata of, as determined by Irradiation with X-Rays, A. G. Marshak, 120
Gaza: Ancient. 4: Tell el Ajjūl, Sir Flinders Petrie (*Review*), 623
Genetic Females, Experimental Transformation of, into Intersexuals, Produced by the Injection of Male Hormone into Fowl Embryos, E. Wolff, 1039
Genetics: Recent Developments in, Prof. T. H. Morgan (Nobel lecture), 292; of Size and Form Factors, Sinnott and Dunn, 347; Human, and Human Ideals, Prof. J. B. S. Haldane (Sir Halley Stewart Trust lecture), 804
Genic Loci, Unstable, Behaviour of, C. Stern, 120
Geographer, The Recollections of a, E. A. Reeves (*Review*), 282
Geological: Congress, International, 18; Survey and Museum: ceremonial opening of new museum, 75; Survey: of Great Britain, Dr. Bernard Smith appointed director of the, 96; retirement of Sir John Flett; appointments at the, 542; Society: New Session of the [1835], 730; of London, election as foreign members of Prof. C. P. Berkey and Prof. P. D. Quensel and of Prof. F. Broili and Dr. E. P. de Oliveira as foreign correspondents, 863
Géologie appliquée, Prof. E. Raguin (*Review*), 970
Geology: as a School Subject, 708; Engineering, a Comprehensive Treatise on, Dr. C. S. Fox (*Review*), 970; Useful Aspects of, Prof. S. J. Shand. Second edition (*Review*), 970
German: Universities and Nazi aims, 41; Books and Periodicals, Reduction in price of, 510; Röntgen Society, election as honorary members of, Dr. A. Béclère, Prof. R. Jaksch-Wartenhorst, A. C. Thurston Holland, Dr. J. M. W. Morison and Dr. Pfahler, 473; Naturalists, Association of [1835], 524; Chemical Industry, 580; Society of the History of Medicine, Prof. W. Haberling awarded the Sudhoff medal of the, 678
Germanium, Raman Spectra of the Bromine Compounds of, and of Tin, A. Tchakirian and H. Volkringer, 43
Germany: The Scientific Association of [1835], 79; Express Highways in, 429; Manufacture of Machinery in, [1835], 963; "Purging" Scientific Literature in, 1021
Germinating Seeds, Action of Metals at a distance on, G. A. Nadson and Mme. Catherine Stern, 349
Geysir at Hawkdale, Iceland, Re-awakening of, 366
Glacial Geology of Holderness and the Vale of York, S. Melmore, 800
Glasgow University: Prof. D. MacCallum Blair appointed regius professor of anatomy, 405; Dr. E. Hindle appointed regius professor of zoology, 654
Glass: Ultra-Violet Transmitting, Pilkington Bros., Ltd., 60; Non-annealed, Variation of the Refractive Index of, as a Function of the Time, Mlle. Niuta Klein, 487
Glazed Stones, H. L. Beck, 440
Gloucester, Romano-British, C. Green, 875
Glue Tests, New British Standard, 1033
Glycogens, Fish and Rabbit Liver, Dr. D. J. Bell, 184
Glyoxalase Activation by Glutathione, Mechanism of, J. Giršavičius, and P. A. Heyfetz, 645
Gmelins Handbuch der anorganischen Chemie, achte Auflage. System-Nummer 35. Teil A, Lief. 2; Teil B, Lief. 2 (*Review*), 854
God and Creation: God, a Cosmic Philosophy of Religion, Prof. J. E. Boodin (*Review*), 597; Three Interpretations of the Universe, Prof. J. E. Boodin (*Review*), 597
Goethe medal for science and art, Prof. O. Lehman awarded the, 985
Gold: Palladium and, Isotopic Constitution of, Prof. A. J. Dempster, 65; Isotopic Constitution of, from Band-spectroscopic Examination, Dr. S. Imanishi, 476
Goodyear and India Rubber Manufacture, [1835], 1001
Gorilla Skulls in the Bristol Museum, H. Tetley, 642
Goulburn District, Geology of the, with special reference to Palæozoic Stratigraphy, G. F. K. Naylor, 449
Government: Laboratory, Activities of the, 215; Chemist, Report of the, for year ending March 31, 1935, 676
Governments, Despotic and Democratic, H. W. Stewart, 947
Gramineae: The, a Study of Cereal, Bamboo and Grass, Dr. Agnes Arber (*Review*), 317
Grapes, Culture of, by Lord Tyrconnel [1835], 882
Grass: Land Problems in South Africa, 266; and other Fodder Crops, Preservation of, 790; and Butter Carotenes, Adsorption of, on Alumina, A. E. Gillam and M. S. el Ridi, 914
Grasses (*Review*), 317
Grasshopper: Locust and, Outbreaks, Rainfall-Evaporation Ratio in relation to, Dr. J. Davidson, 298; Colour Changes in the Eye of a, H. Uchida, 481; Abdominal Mechanisms of a, R. E. Snodgrass, 918
Gravimetric Linking of European Stations of Reference, A New, P. Lejay, 883
Great: Barrier Reef, Zooplankton of the, F. S. Russell and J. S. Colman, 194; Western Railway, Centenary of the, 367
Green Fly, Epidemic of, 17
Greenland: West, Native Iron from, Sir Harold Carpenter, 152; Bibliography of, H. Vartdal, 295; East, The Fiord Region of, Louise A. Boyd and others (*Review*), 594; North-East, Caledonian Orogeny of, C. E. Wegmann, 725
Green's Night in a Balloon [1835], 448
Greenwich Catalogue of Stars, Second, for 1925.0, 306
Grey of Fallodon, Viscount, proposed memorial to the late, 827
Grime's Graves, Norfolk, Flint-mining at, A. L. Armstrong, 687
Gryllides and Tettigoniides from the Anglo-Egyptian Sudan, R. Erner, 274
Guanine in the Excreta of Arachnids, K. Vajropala, 145
Gymnosperms: Structure and Evolution, Prof. C. J. Chamberlain (*Review*), 278

H+ ions in the Phenomena of [Reduction and Hydrogenation, Influence of, A. A. Guntz and E. Beltran, 157
Habrobracon, Determination of Sex in, G. D. Snell, 488
Hæmatopoietic Liver Substance, Dr. H. D. Dakin and West, 97
Hæmoglobin, Oxygen Equilibrium of, and its Structural Interpretation, L. Pauling, 120
Hake, The, and the Hake Fishery: being the Buckland lectures for 1934, C. F. Hickling (*Review*), 776
Half Mile Down, Dr. W. Beebe (*Review*), 586
Halley's Comet: Reappearance of [1835], 195; seen in England [1835], 310; Littrow observes [1835], 525
Hardwood Trees, Our British Grown, A. L. Howard, 509
Harmonic Oscillator, Uncertainty Principle and the Zero-point Energy of the, R. A. Newing, 395
Harrison Memorial Prize, 1935, award of the, to Dr. L. E. Sutton, 984
Harrison's Chronometers at the Science Museum, 216
Harvard University: Dr. E. D. Merrill appointed head of the botanical department, 333; Physical Laboratories of, Contributions from the. Vol. 22, 390
Harze, Die, A. Tschirch und E. Stock. Dritte Auflage von A. Tschirch: Die Harze und die Harzbehälter, Band 2, Hälfte 1 (*Review*), 625
Hawaii, Marine Worms from, M. Holly, 189
Health: A New Angle on, Surg.-Capt. D. H. C. Given (*Review*), 282; Public, Fifty Years in: a Personal Narrative with Comments, Sir Arthur Newsholme (*Review*), 596; Ministry of, Report for 1934–35, 639; Food Supplies and, 657

Hearing and Aids to Hearing, A. F. Rawdon-Smith and others, 483
Heats, Specific and Latent, The Discovery of, Dr. D. McKie and N. H. de V. Heathcote (*Review*), 244
Heavy Water: Surface Tension of, H. Lachs and I. Minkow, 186; Supersaturated Vapour of, Formation of drops in, Dr. L. Tronstad and H. Flood, 476; Density of 100 per cent, Dr. L. Tronstad, J. Nordhagen and J. Brun, 515; Raman Spectrum of, R. Ananthakrishnan, 551; Diffusion of, into ordinary Water, M. Temkin, 552
Heisenberg theory of Ferromagnetism, A Refinement of the, applicable to Simple Cubic Crystals, C. H. Fay, 769
Helium: 3 in quantity, Attempts to produce, Prof. F. A. Paneth and Prof. G. P. Thomson, 334; Content of the Stratosphere, Prof. F. A. Paneth and E. Glückauf, 717
Helotrephidæ, Aquatic Hemiptera of the family, W. E. China, 189
Herbarium Material, Biometrical Studies on, Dr. E. Anderson and Dr. W. B. Turrill, 986
Herculis, Nova: Distance of, E. G. Williams, 442; Resolution of, 1934, F. Baldet, 487
Hermit-Crab, Oogenesis of a, Seasonal Variation in, M. K. Subramaniam, 265
Herpetology: Popular and Systematic, Dr. H. B. Cott (*Review*), 529
Herring: Research, The Advance of, E. Ford, 896; Phytoplankton and the, Part 1, R. E. Savage and Prof. A. C. Hardy, 962
Hessian Fly, Germ-cell Cycle in the, Margot E. Metcalfe, 440
Heterogonic Growth, A Useful Application of the Principle of, A. E. Needham, 433
Hexadecane, Normal, Autoxidation of, G. Arditti, 525
Hexadeuterobenzene: Vapour Pressure of, Dr. C. L. Wilson, 301; Infra-Red Spectrum of, and the Structure of Benzene, Dr. W. R. Angus, C. R. Bailey, Prof. C. K. Ingold, A. H. Leckie, C. G. Raisin, J. W. Thompson and Dr. C. L. Wilson, 680
High-Frequency Discharge, Initiation of the, Dr. J. Thomson, 300
Himalayan Expedition, A (*Review*), 1005
Hispano-Belgian scientific *entente* committee, Prof. G. Maranón elected president of the, 678
Hittite Art, Prof. E. Herzfeld, 469
Holland, Royal Colonial Institute of, Annual Report, 790
Home Economics, Fundamentals in Teaching, Ivol Spafford (*Review*), 664
Homeotherms, Resistance of some, to Low Temperatures, J. Giaja and S. Gelineo, 197
Homologous Loci and Chromosome Conjugation, Forces of Attraction of, Dr. B. N. Sidorov, N. N. Sokolov and I. E. Trofimov, 108
Hong-Kong and South China, Science in, 473
Hooke, Robert: Tercentenary of, 1635–1703, 56; and his Contemporaries, Prof. E. N. da C. Andrade, 358; The Diary of, Edited by H. W. Robinson and W. Adams, 358; and his Contemporaries, T. E. James; Dr. R. T. Gunther; Prof. E. N. da C. Andrade, 603; Commemoration of, at Oxford, 863
Horse, Domesticated, Origin of the, Dr. M. Hilzheimer, 111
Horses, Skull in, Evolution of the, Dr. R. C. Robb, 304
Horticultural Society, The [1835], 118; 654
Housing and Overcrowding, Circulars on, 948
Hoxne, Suffolk, Investigations at, J. Reid Moir; Dr. G. Erdtman, 227
von Humboldt, Alexander, in Paris [1835], 272
Human: Abilities, Factorial Analysis of, Prof. G. H. Thomson, 34; Origin and Christian Doctrine, Dr. W. D. Lang, 168; Genetics and Human Ideals, Prof. J. B. S. Haldane (Sir Halley Stewart Trust lecture), 804; Evolution, Head, Heart and Hands in, Dr. R. R. Marett (*Review*) 815; Foot, Evolution of the, H. Eletman and J. Manter, 957
Humanism, Scientific, 965
Humanistic Science, 885
Hungarian Academy of Science, election of Baron A. Koranyi as an honorary member of the, 27
Hunger-contractions and Rate of Conditioning, M. H. Elliott and W. C. Treat, 564
Hutchinson's Technical and Scientific Encyclopædia. Edited by C. F. Tweney and I. P. Shirshov. Vol. 2 (*Review*), 166
Huxley, Thomas Henry, The place of, in Anthropology, Sir Grafton Elliot Smith (Huxley memorial lecture), 863
Hyacinths, British-grown, D. E. Horton, 305
Hydraulic Couplings: and Torque Converters, 77; Recent Developments in, H. Sinclair, 77
Hydrocarbons, Fatty, Catalytic Decomposition of the Monobromo Derivatives of, J. B. Senderens, 234
Hydrocyanic Acid, Formation of, J. Parrod, 1002
Hydrogen: in the Upper Atmosphere, Prof. J. Kaplan, 549; Explosive Potential of, with High-frequency Current, R. Zouckermann, 807; Oxygen Mixture, Mechanism of the Chain Reaction of the, M. Prettre, 844; with Oxygen, Reaction of, G. A. Cook and J. R. Bates, 877
Hydrogenation of Coal, 855
Hydrographie, Prof. F. Schaffernak (*Review*), 815
Hydrolysing Diastases, Destruction of Certain, in the Course of their Action, R. Bonnet and Mlle. Berthe Nataf, 1039
Hydromechanics, A Treatise on. Part 2: Hydrodynamics, A. S. Ramsey. Fourth edition (*Review*), 598
Hydrophobia, Jubilee of the Prevention of, produced by a Bite, F. Mesnil, 883
Hygiene, Industrial, Problems of, H. B. Butler, 159
Hygrometric State of the Air, Variation of the Length of Cement as a function of the, M. Lucas, 311
Hymenomycetes, Sexual Fusion in, Cytological significance of the, Prof. S. R. Bose, 873
Hypergeometric Series, Generalised, Dr. W. N. Bailey (*Review*), 595
Hystricoid Rodents of the Neotropical Region, G. H. H. Tate, 441

Ice: Age, The Changing World of the, Prof. R. A. Daly (*Review*), 491; Accretion on Aircraft, Lockspeiser, 904
Ideal- und Real Kristall (*Review*), 165
Illuminating Engineering, Future of, A. W. Beuttell, 714
Illumination: and Efficiency, H. C. Weston, 648; A Symposium on, J. F. Colquhoun and others. Edited by C. J. W. Grieveson (*Review*), 775; Practical Aspects of (*Review*), 775; Physiology of, Dr. R. J. Lythgoe, 877
Imperial: Social Hygiene Congress, Biology at the, 116; Institute, Annual Report, 255; Mycological Conference, Third, 269; Agricultural Bureaux, Fifth Annual Report of the, 389; Botanical Conference, 402; Airways New Programme, Sir Eric Geddes, 787; Chemical Industries, Ltd., Reduction of Capital, 828; Cancer Research Fund, Work of the, Dr. W. E. Gye, 945
Implementiferous Gravels of the Vaal River at Riverview Estates, Prof. C. van Riet Lowe, 53
Incomplete Circular Ring, Vibration of an, T. Ikeho, 959
India: a Prehistoric Discovery, U. Thakur, 136; Broadcasting in, 230; Evaporation in, P. K. Raman and V. Satakopan, 267; Mechanical Cultivation in, C. P. G. Wade, 293; an Earthquake Research Commission for, 907
Indian Ocean, the Deep-water Circulation of the, A. J. Clowes and G. E. R. Deacon, 936
Indol, Sulphur Derivatives of, A New Synthesis of, M. H. Wuyts and Miss A. Lacourt, 655
Inductance, Capacitance and Frequency, The Measurement of, A. Campbell and Dr. E. C. Childs (*Review*), 453
Industrial: Hygiene, Problems of, H. B. Butler, 159; Solvents, Toxicity of, 177; Health Research Board, Prof. J. A. Nixon and Dr. R. E. Lane appointed members of the, 256; Power in Great Britain, F.

Forrest, H. Hobson and C. Taite, 471; Reorganisation and International Obligations, Lord Davies (*Review*), 735; Psychology, Some Problems of Feeding in Relation to, D. Katz, 875
Industry: Organisation of, 237; Science and Leadership in, 313; Scientific Direction in, Neglect of, 323; and the Public Library Services, Co-operation between, R. Brightman and others, 558; and Technical Education, Oliver Stanley, 902; Health and Safety in, 928
Inefficiency, a Standardisation of, 982
Inequalities, Prof. G. H. Hardy, Prof. J. E. Littlewood and G. Pólya (*Review*), 315
Inflammable Gas-Air Mixtures, Influence of Pressure on the Spontaneous Ignition of, D. T. A. Townend and E. A. C. Chamberlain (4), 882
Insect: -Population, Experimental Analysis of the Growth of an, S. MacLagan and E. Dunn, 196; Parasites, Host Selection by, G. Salt, 400; Morphology, Principles of, R. E. Snodgrass; Dr. A. D. Imms (*Review*), 812; Wings, Primitive Colour-pattern of, H. Lemche, 958
Insects, Instructions for Collectors, No. 4. Eighth edition. 949
Instrument Making, English, in the 18th Century, Dr. R. S. Clay and T. H. Court, 982
Insulin Inhibiting Agency in the Duodenum, An, Prof. A. B. Macallum, 32
Intelligence Test, General, and its Norm, Dr. H. Kirihara, 227
Intermediate Sex Forms, Experimental production of, by the injection of Folliculin in the Embryo of the Fowl, E. Wolff and A. Ginglinger, 197
Internal: Secretion, Physiology and Pathology of (*Review*), 355; Combustion Engine and its Fuel, Progress of the, H. R. Ricardo (Melchett lecture), 714
International: Science, Nazi-Socialism and, 927; Geological Congress, 1937, 1024
Intertidal Ecology, Kitching, 519
Inverse Probability, Dr. T. E. Sterne; Dr. H. Dingle, 301
Invertebrate Animals, Exclusive of Insects, A Manual of the Common, Prof. H. S. Pratt. New edition (*Review*), 1010
International: Broadcasting Union, Annual Meeting, 61; Medical Post-Graduate Congress, 64; Congress on Population Problems, 100; Conference on Folk Dancing, 135, 154; Congress of Soil Science, Third, 139; Astronomical Union, Fifth General Assembly, 193; Physiological Congress, Fifteenth, Dr. D. Y. Solandt, 571; Botanical Congress, Sixth, Dr. A. B. Rendle, 612; Congress of Zoology, Twelfth, 612; Meteorological Conference, 613; Congress of Mining, Metallurgy and Applied Geology, Seventh, 677
Iodine: for Livestock, F. Corrie, 27; -Amylum Reaction, G. van Iterson, Jr., and J. Coumou, 617; in Biological Substances, Determination of, C. O. Harvey, 920
Ionic Disperse Systems, Extension of the theory of Complex Coacervation to, H. R. Kruyt and H. G. Bungenberg de Jong, 617
Ionisation, 'Bursts' of, caused by the Cosmic Rays, Application of Dielectric Liquids to the study of the, C. Białobrzeski and I. Adamczewski, 157
Ionosphere: Theory of the, H. G. Booker, 229; Measurements of the Reflective Coefficient of the, for Wireless Waves, F. W. G. White and L. W. Brown, 806; Electrons in the, Frequency of Collisions of, T. L. Eckersley, 953
Ireland: and the British Association [1835], 348; The Botanist in, Dr. R. Lloyd Praeger (*Review*), 592; Culture and Peoples of (*Review*), 886; Prehistoric Man in, Dr. C. P. Martin (*Review*), 886
Iridium: Isotopes and their Nuclear Spin, Prof. B. Venkatesachar and L. Sibaiya, 437; Isotopic Structure of, Prof. A. J. Dempster, 909
Iris, Diseases of the, G. N. Bunyard, 266
Irish Radium Committee, Report for 1934, 294
Iron: and Steel, Sir William J. Larke, 14, 19; Native, from West Greenland, Sir Harold Carpenter, 152; Age Pottery in Britain, Dr. R. E. M. Wheeler, 265; -Nickel-Chromium-Carbon Austenite, Hypertempered, Accelerating Effect of a Sinusoidal Mechanical Tension on the Changes in a, P. Chevenard and X. Waché, 448; Transition, Cinematograph Record of the $\alpha \rightleftarrows \gamma$, as seen by the Electron-Microscope, Dr. W. G. Burgers and J. J. A. Ploos van Amstel, 721; Oxide Sols, Certain, Distances between the Colloidial Particles in the Bright Layers of, W. Hiller, 924
Irrigation for Horticultural Market Crops, F. A. Secrett, 228
Isocyanic α-Ethylenic Esters of the formula R.CH=CR'.N=C=O, A General Method of Synthesis and the Chemical Properties of the, J. Hoch, 844
'Isopolles', Method of, applied to researches on the history of Trees and Forests, W. Szafer, 845
Isotopes, The Story of, Dr. F. W. Aston, 380
Isotropic Transparent Solids, Measurement of the Elastic Constant of, Dr. E. Hiedemann, 337
Italian: Breakwater Construction, Prof. E. Coen Cagli, 99; National Council of Research, Activities of the, 177; Seismological Society, History of the, Prof. G. Agamennone, 256
Italy, Education in [1835], 882

Jan Mayen, Austrian Polar Expedition to, 1932–33, Terrestrial Magnetic Observations of the, R. Kanitscheider, 450
Janvier, Antide, Death of (1751–1835), 487
Japan: Mortality in, Influence of Industrialism on, 429; Typhoon of September 21, 1934, 544
Japanese Biological Publications, 294
Jehol, Crustacea of, M. Uéno; T. Sakai; H. Uchida, 957
Jensen Rat Sarcoma, Growth of the, Influence of certain Polycyclic Hydrocarbons on the, A. Haddow, 868
Jubilee Naval Review, Broadcasting and the, 97

Kaiser-Wilhelm-Gesellschaft zur Förderung der Wissenschaften, Work of the, 271
Kalahari Expedition, Insects of the, 876
Kashmir, Linguistic Research in, Col. D. L. R. Lorimer, 638
Kelsey and Gaviota Plums, Effect of Time of Picking on the Chemical Changes of, I. Donen, 157
Kelvin and the Age of the Sun, C. Turnbull, 761
Kelvin's 'As if' in Physics, Prof. W. Peddie, 955
Kenya: the Settler's Story, Rt. Hon. W. Ormsby-Gore (*Review*), 161
Keratin, Structure of, W. T. Astbury and W. A. Sisson, 557
Kerr, The Rev. John, F.R.S., Inventor of the Kerr Cell, 245
Khanki Weir, Protection below (2), J. P. Gunn, 959
Kieselguhr, Adsorption of Aluminium Hydroxide by, Prof. E. C. C. Baly and W. P. Pepper, 28
Kiln-drying of Wood with Ozonised Air, S. N. Kapur, 151
King's Fund Miniature Hospital, 714
Kinsenda (Belgian Congo), Copper minerals of, M. Gasin (3), 312
Kisi of Liberia, Miss E. D. Earthy, 724
Klebs, Edwin, work of, Dr. L. Baumgartner, 675
Kmer Art and the Cultures of Precolumbian America, H. Marchal, 440
Koch, Robert, medal, award of the, to Prof. F. Sauerbruch, 547
Kodachrome Film, Eastman Kodak Company, 98
Kükenthal and Krumbach's Zoology (*Review*), 241
Kulturwissenschaftliche Bibliographie zum Nachleben der Antike. Band 1: Die Erscheinungen des Jahres 1931 (*Review*), 658

Lac and the Indian Lac Research Institute, D. Norris, F. M. Glover and R. W. Aldis, 545
Lake: Geneva, Mollusca of, J. Favre, 518; Huleh, the Percy Sladen Expedition to, 538
Lamps, New 'House Number', 389

Land: Speed Record, New, Sir Malcolm Campbell, 390; -Snails, A Warty Growth on the Head of, I. Taki, 399
Landfall of Columbus: Lieut.-Comdr. R. T. Gould, 559; Possible Bearing of a Luminous Syllid on the question of the, L. R. Crawshay, 559
Lankester, Sir Ray, as Archæologist (*Review*), 356
Laplace, Monument to, [1835], 963
Law and the Social Sciences, H. Cairns (*Review*), 934
Leander McCormick Observatory, Analysis of 18,000 Proper Motions derived at the, P. van de Kamp and A. N. Vyssotsky, 488
Leathersellers' Technical College, impending retirement of M. C. Lamb, 1024
Leather Trades' Chemists, International Society of, Conference of, G. Colchen elected president for 1936–37, 443
Lecithin as a Dispersing Agent for Dibenzanthracene, H. D. Barnes, 756
Leeds University: gift by H. S. Clough, 155; F. S. Atkinson appointed professor of mining, 730; Report for 1934 of the Department of Pathology and Bacteriology, 984
Legendre Functions, Some Series and Integrals involving associated, regarded as Functions of their Degrees, T. M. MacRobert, 196
Leisure: Education and, in Progressive Life, 847; The coming of, the Problem in England. Edited by E. B. Castle, A. K. C. Ottaway and W. T. R. Rawson, 847
Lenses employed in the Technicolor Process of Cinematography, H. W. Lee, 879
Leonids, The, 866
Leptinotarsa decemlineata, Variations of Fertility of, with the Tuber Producing *Solanum* consumed by the Insect, B. Trouvelot and Grison, 1039
Leverhulme Research fellowships and grants, 100
Leyden University, Establishment of a Foundation for Theoretical Biology in, 99
Librarian, The Profession of, B. M. Headicar (*Review*), 280
Liebig medal, award of the, to Prof. W. Roth, 547
Life: Rate of Growth and Length of, H. C. Sherman and H. L. Campbell, 197; in Isolated Animal Organs, Maintenance of, Carrel and Lindberg, 628; and Philosophy, a Poet's Picture of, Mrs. C. A. F. Rhys Davids (*Review*), 813; the Molecules of (*Review*), 1006
Light, The Diffraction of, X-Rays and Material Particles: an Introductory Treatment, Prof. C. F. Meyer (*Review*), 597
Lighting Calculations, Prof. H. H. Higbie (*Review*), 775
Lightning: Progressive, Dr. B. F. J. Schonland, D. J. Malan and H. Collens (2), 42; Stroke, Return, Intensity Variations in the Channel of the, D. J. Malan, Dr. B. F. J. Schonland and H. Collens, 831; Stroke Currents, P. L. Bellaschi, 961; Discharge, Recent Progress in the Study of the, Dr. B. F. J. Schonland, D. J. Malan and H. Collens, 1039; Stroke, Intensity Variations in the Main Return, D. J. Malan, 1039
Lime Light, Experiments with the [1835], 195
Lindsay's, James Bowman, Electric Light Experiments [1835], 118; 693
Line Standards, Precision of, A. Pérard, 104; Dr. W. E. Williams, 105
Linguistics, Experimental, Prof. E. W. Scripture (*Review*), 455
Linnean Society of London, election of the King of the Belgians as honorary member of the, 786
Liquid Dielectrics, Cosmic Ray Bursts in, Prof. C. Białobrzeski and I. Adamczewski, 109
Liquids, Dielectric Constant of: Magnetic Change of the, A. Piekara and M. Schérer, 487; at Radio Frequencies, Dr. D. Doborzynski, 801
Liverpool: University: Prof. T. B. Abell appointed pro-vice-chancellor; J. F. Craig appointed William Prescott professor of the care of animals, 117; Dr. H. H. Stones appointed Louis Cohen professor of dental surgery and director of dental education in 447; Science Exhibition at, 712
Living Things: an Introduction to Biology, R. Palmer (*Review*), 591
L.M.S., New Research Laboratory of the, Opening of, 949; 997
Lobsters, Growth and Moulting of, W. C. Smith, 763
Lockyer, Norman, Observatory, Handbook of the, Dr. W. J. S. Lockyer. Second edition, 472
Locust and Grasshopper Outbreaks, Rainfall-Evaporation Ratio in relation to, Dr. J. Davidson, 298
Locusta migratoria, L., Effects of X-Rays on Mitosis in the Spermatogonial Divisions of, M. J. D. White, 844
Locusts and Grasshoppers, Dr. B. P. Uvarov, 653
Lodge, Sir Oliver, F.R.S., A Bibliography of, T. Besterman (*Review*), 357
London: Transport Scheme, 16; Hospital, Collected Researches, 1934; 390; and Greenwich Railway, Progress of the [1835], 406; School of Economics, the department of business administration, 447; Life and Labour, The New Survey of. Vol. 9: Life and Leisure (*Review*), 695; Mechanics' Institution [1835], 882; University: award of University post-graduate travelling studentships to R. G. R. Bacon and A. E. J. Went and of the University studentship in physiology to R. A. Gregory, 79; Dr. J. Whillis appointed reader in anatomy at Guy's Hospital Medical School; Dr. J. Neyman reader in statistics at University College; conferment of title of professor of statistics on Dr. E. S. Pearson; award of the Sir George Jessel studentship in mathematics to A. E. Chapman; E. P. Stibbe appointed reader in anatomy at King's College, 156; title of professor of Egyptology conferred on S. R. K. Glanville and that of emeritus professor on Prof. J. W. H. Eyre and Prof. A. H. Jameson, 730; presentation of the Petrie medal to the Abbé H. Breuil, 861; Dr. E. Boyland appointed reader in biochemistry at the Cancer Hospital; Dr. V. B. Wigglesworth appointed reader in entomology at the London School of Hygiene and Tropical Medicine, 881; College: Chemical and Physical Society of, 637; Courses of the School of Librarianship at, 843
Longer Trade Cycles, The, A. F. Enström, 292
Longitude Operations, International, 445
Loris in Captivity, Breeding of, Prof. W. C. O. Hill, 107
Low Temperature: Research—Its Objects and Methods, Prof. F. Simon, 16; Physics, Dr. L. C. Jackson (*Review*), 854
Lower Oligocene Mammal-bearing Beds near Death Valley, California, Occurrence of, C. Stock and F. D. Bode, 925
Lubrication, 504
Lulham Memorial Fund, proposed, 98
Lumbricus, Regulation of the Breathing of, J. B. Thomas, 235; Cytoplasmic Bodies in the Oogenesis of, Miss Gertrude Norminton and Prof. J. B. Gatenby, 916
Lumière and the Invention of Cinematography, 803
Lummer Plate, Use of a, J. H. Gisolf, 617
Lunar: Heights and Topography, McMath, Petrie and Sawyer, 190; Atmospheric Pressure Inequalities at Glasgow, The, R. A. Robb and T. R. Tannahill, 800
Lung-fish, South American, Breeding in Capacity of the, C. W. Parsons, 954
Lyell: and Sir John Herschel [1835], 41; and the Continental Geologists [1835], 118; in Switzerland [1835], 348; and Mantell [1835], 616; Agassiz and Deshayes [1835], 654
Lyginorachis, Kidston, The genus, Mary G. Calder, 196
Lysholm-Smith Torque Converter, Progress in design and application of the, Haworth and Lysholm, 77

MacAlister of Tarbert, Sir Donald, by his Wife. With chapters by Sir Robert Rait and Sir Norman Walker (*Review*), 929
Macaque: Analytical Character of Perception in the, L. Verlaine, 655; (2), 845
Macculloch, John, F.R.S., Death of [1835], 272
McGill University, Montreal, Prof. A. Norman Shaw appointed head of the physics department and director of the Macdonald Physics Laboratories, 156

Madagascar, Crystalline Massif of, Magnetic Anomalies of the, H. Greyelle and C. Poisson, 311
Madras Fisheries, Report on, Dr. B. S. Raj, 389
Madrid University, conferment of honorary doctorates on Prof. M. Caullery, Dr. R. Goldschmidt, Dr. R. Jeannel, Prof. F. Silvestri and B. P. Uvarov, 729
Magnesium: Oxide, Crystalline, Properties of, Prof. R. W. Ditchburn and J. Harding, 70; and Sodium, *K*-Series of, Dr. V. Kunzl, 437; with Methylene Blue, Volumetric Microdetermination of, following its Precipitation as Magnesium Picrolonate, A. Bolliger, 449
Magnetic: Susceptibility of Metals, Change of, during Melting and Allotropic Transformation, Prof. K. Honda and Y. Shimizu, 393; Storms and Upper-Atmospheric Ionisation, Prof. E. V. Appleton and Miss L. J. Ingram, 548; Susceptibility of mixed Oxides of the Rare Earths, L. Mazza (1), 1040
Magnetism: and Matter, Dr. E. C. Stoner (*Review*), 88; Modern Views on (*Review*), 88; a Christmas Experiment in, [1835], 1000
Mahābhārata, The Mystery of the, N. V. Thadani. 5 Vols. (*Review*), 813
Mahajamba River of Madagascar and its Temporary Captures by the Kamoro, R. Decary, 1002
Maiden Castle: Recent Excavations at, Lieut.-Col. C. D. Drew, 155; Excavations at, 290
Maimonides and his Works, Dr. M. Gaster, 829
Maize, Location of a Gene for Disease Resistance in, Virginia H. Rhoades, 197
Malaria, Chemotherapy of, Col. S. P. James, 539; 743
Malnutrition, Committee against, 97; 984
Mammals, Migrations of, Prof. J. Ritchie and others, 500
Man: Again ?, Origin of, W. W. L., 106; and Woman: a Study of Secondary and Tertiary Sexual Characters, Havelock Ellis. Eighth edition (*Review*), 124; in America, Origins of Man, E. B. Howard, 175; The Birthplace of, Sir Arthur Smith Woodward, 384; Early: Recent Progress in the Study of, Sir Arthur Smith Woodward, 419; in East Anglia, Geological Relations of, Dr. J. D. Solomon, 502; and the Universe, Sir James Jeans (Sir Halley Stewart Trust lecture), 689; in Industry, Physique of, Prof. Cathcart and others, 1023
Management, The Profession of, W. R. Dunlop, 340
Manakins, Courtship of, F. M. Chapman, 957
Manchester College of Technology, the Department of Industrial Administration, Dr. K. G. Fenelon, 524
Manchukuo, Neolithic Civilisation of, I. Yawata, 762
Mandelic Acid: a Urinary Antiseptic, M. L. Rosenheim, 401; in Urinary Infections, 482
Mankind, the Geographic Pattern of, Dr. J. E. Pomfret (*Review*), 935
Mannitodimolybdic Acid, Mme. Zina Soubarew-Chatelain, 119
Manometer, A Recording, having low Inertia, G. Allsop and H. Lloyd, 151
Map: Unrolling the, the Story of Exploration, L. Outhwaite (*Review*), 701
Marine: and General Engineering, Fifty Years' Progress in, 129; Organisms in the Laboratory, An apparatus for Rearing, Dr. F. G. Walton Smith, 345; Plankton of the Coastal Waters of New South Wales, Prof. W. J. Dakin and A. Colefax, 958
Markleeberg Palæolithic Industry, Geological Age of the, R. Grahmann, 518
Marquesan Shell Coronet, 188
Marriage Hygiene, 175
Mars, Planet, Recent Observations of the, E. M. Antoniadi, 311
Masaryk, President, and Technology, 292
Matairesinol, Constitution of, L. H. Briggs, D. A. Peak and J. L. D. Woolloxall, 273
Material Mass and the Magnetic Mass, The principle difference between the, L. Schames, 273
Materie, zusammenhängenden, Aufbau der, Redigiert von A. Smekal (*Review*), 973
Mathematical: Analysis, Modern, The Basis of (*Review*), 315; Sciences in France a Century Ago, Baron Charles Dupin, 1037
Mathematics: The Foundations of, Prof. L. M. Milne-Thomson (*Review*), 126; and Materialism (*Review*), 493
Mathematik im Dienste der nationalpolitischen Erziehung, mit Anwendungsbeispielen aus Volkswissenschaft, Geländekunde und Naturwissenschaft, Herausgegeben von A. Dorner (*Review*), 281
Mathématique, esquisse du progrès de la pensée, J. Pelseneer (*Review*), 415
Matrices, Lectures on, Dr. J. H. M. Wedderburn (*Review*), 595
Matter, The Electronic Structure and Properties of, C. H. D. Clark (*Review*), 127
Maury's work on Navigation [1835], 693
May-flies, Development of, F. P. Ide, 519
Meare Lake Village, 1935, 469
Mechanical: Engineering, Textbook of (*Review*), 89; Stresses at Higher Frequencies, New Methods of measuring, Dr. A. Bloch, 223; Inventions, The Germs and Development of some, C. F. Dendy Marshall, 749
Mechanisation in Industry, Dr. H. Jerome; R. Brightman (*Review*), 659
Mechanism, Principles of, Prof. C. E. Pearce (*Review*), 244
Medical: Curriculum in Great Britain, The (Report of Conference of Representatives, etc.), 90; Botany of the Eighteenth Century, H. S. Redgrove, 216; Biology, Religious Motives in, Dr. W. Pagel, 367; Research Council: work of the, Miss Norah Dacre Fox, 639; Prof. J. A. Ryle and Prof. M. J. Stewart appointed members of the, 640; Man, The, and the Witch during the Renaissance, Dr. G. Zilboorg (*Review*), 660; Research, Epochs in, Sir Henry Dale (Harveian Oration), 690; Science, Progress in, Prof. E. Mellanby (Sir Halley Stewart Trust lecture), 747
Medicine: Progress of, Spanish influence on, 470; History of, Congress at Madrid, 577; conferment of honorary doctorates, 602
Medico-Botanical Society, Meeting of the [1835], 768
Mediterranean Fruit Fly, Biological Control of the, 1023
Melchett medal of the Institute of Fuel, Presentation of the, to H. E. Ricardo, 640
Mellon Institute: Nutrition Research at the, 63; Twenty-second Annual Report, 291; Scientific Investigations at the, Dr. E. R. Weidlein, 789
Mercury: Arcs, Light Emission of, under High Pressure, P. Waguet, 563; Isotopes, Separation of the, by a Photochemical Method, Dr. K. Zuber, 796
Metabolism, Effects of Prolonged Exercise on, F. C. Courtice and C. G. Douglas, 1001
Metallic: State, The, Dr. J. A. Prins and others, 115; Salts, Molecular Emission Spectra of some, P. Mesnage, 196; Fluorides, Action of Steam on some, L. Domange, 234
Metallurgy: an Elementary Text-Book, E. L. Rhead. New edition (*Review*), 8
Metals: in Food, 18; Hardness of, and its Measurement, Dr. H. O'Neill (*Review*), 415; in the Chemical Industry, Dr. C. H. Desch, 751; Oxidation of, G. D. Preston and L. L. Bircumshaw, 764
Metaphysics of the Physical World, Prof. V. F. Lenzen, 433
Meteoritenkunde, Kleine, Prof. F. Heide (*Review*), 128
Meteor Trail of March 24, 1935, Photographs of Bright, Dr. W. Bleeker, 224
Meteorites, Falling, Records of Fatalities from, M. A. R. Khan; the Writer of the Review, 607; Dr. A. M. Heron, 1030
Meteorological: Conference, International, 613; Office, Report for year ending March 31, 1935, 636
Meteorology: A Manual of the Principles of, R. M. Deeley (*Review*), 205; Physical and Dynamical, Prof. D. Brunt (*Review*), 240; Mathematical Methods in, Prof. J. Bjerknes (*Review*), 240
Meteors, Recent Shower of, 867
Methane, Oxidation of, Initial Formation of Methyl Alcohol in the, Prof. W. A. Bone, 910
Methyl: Alcohol, Action of Calcium Carbide on, Prof. A. Contardi and Dr. B. Ciocca, 190; Iodide, Absorption Spectrum of, N. S. Bayliss, 264; Alcohol, Initial Formation of, in the Oxidation of Methane, Prof. W. A. Bone, 910

Methylcyclohexanols, *cis-trans* Isomerism of the, Application of the Raman Effect to the Study of the, J. Tabuteau, 964
Methyldiethylcarbinol, Raman Spectra of, J. Savard, 925
Methylene Blue as a Stain for Mucus, A. G. Lowndes, 398
Metropolitan-Vickers Laboratories, The, 673
Michigan University, gift to, by the Rockefeller Foundation, 716
Micro-Incineration Studies, F. M. Uber and T. H. Goodspeed (1), 488
Microscope Technique, Prof. J. B. Gatenby, 723
Microtechnique, Elementary, H. A. Peacock (*Review*), 592
Mid-Ice: the Story of the Wegener Expedition to Greenland, Dr. J. Georgi. Translated by F. H. Lyon (*Review*), 533
Migrations of Animals, 500
Milk, Pasteurization of, Sir Arnold Wilson, and others, 1
Miller, S. W., medal of the American Welding Society, award of the, to J. C. Lincoln, 254
Minds Diseased, Ministering to (*Review*), 319
Mineral: Oils, Oxidation of, by Gaseous Oxygen at Moderate Temperatures, G. Muller, 43; Sanction, The, as an Aid to International Security, Sir Thomas H. Holland (*Review*), 123; Elements, Return of, to the Soil by Plants, Prof. Deleanu and others; Dr. N. L. Penston, 268; Oils, Critical Temperature of Solutions of, E. Vellinger and J. D. Herrenschmidt, 883
Mine Timber, Preservation of, J. Bryan and N. A. Richardson, 994
Minerals: and International Security (*Review*), 123; and their Utilisation, Sir Thomas Holland, 945
Mines, Safety in, Research Board, Thirteenth Annual Report, 790
Mining Electrical Engineering, A. W. Williams, 472
Minkowski, Back to: (*Review*), 621; Dr. F. W. Lanchester; H. T. H. P., 760
Minos: The Palace of, a comparative account of the successive stages of the Early Cretan Civilization as illustrated by the discoveries of Knossos, Sir Arthur Evans. Vol. 4, Parts 1 and 2 (*Review*), 202
Mitten Crab in English Rivers, 673
Mixtec Indian Manuscript, Miss Emma Reh, 188
Modern Anthropology *versus* Biblical Statements on Human Origin, Sir Ambrose Fleming. Second edition, 168
Molasses and Nitrogen Fixation in Soil, N. R. Dhar and S. K. Mukerji, 400
Molecular: Orientation and the Probability of Dissociation of Molecules by Electron Impact, Prof. N. Sasaki and T. Nakao, 260; Fields in the Liquid State, J. Weigle, 273; Weights by the Ultra-Centrifuge, W. D. Lansing and E. O. Kraemer, 442
Molecules, Molecular Orientation and the Probability of Dissociation by Electron Impact, Prof. N. Sasaki and T. Nakao, 260
Molisch's, Prof. Hans, Recollections (*Review*), 494
Molybdenum, Biological Distribution of, Prof. H. Ter Meulen and Miss H. J. Ravenswaay, 78
Morocco, The Folklore of, Dr. F. Legey. Translated by Lucy Hotz (*Review*), 591
Morse's Rule, Suggested Improvements of, C. H. Douglas Clark and J. L. Stoves, 682
Motor: Fuel Preparation and Application, The Principles of, Prof. A. W. Nash and Dr. D. A. Howes. 2 Vols. (*Review*), 413; Fuels (*Review*), 413; Vehicles, Research on, 482
Mount Everest Expedition, E. E. Shipton, 948; 984
Mount Wilson Observatory, the 200-inch Disk for the, 949
Mouse leukæmia, Transplantable, Dependence of Protection against a, upon the Genetic Constitution of the Immunising Tissue, E. C. MacDowell, M. J. Taylor and J. S. Potter, 564
Mud: Shrimps of the Atlantic Coast of North America, Dr. W. L. Schmidt, 189; -Castle of the Han Dynasty, Chôsen, Y. Harada, 342
Munich, Deutsches Museum at, Busts placed in the, of Robert Koch and Conrad Röntgen, 218
Muscle Fibres, Surface Membranes of, W. L. Francis, 1001
Museums Association, Annual Conference at Brussels, 116
Music, Alchemy and, Prof. J. R. Partington; Prof. J. Read, 107
Mus musculus, Linkage Relations in 'Zavadskaia shaker' in, F. H. Clark, 197
Myosin, Expansion of Films of, on Potassium Lactate, S. A. Moss, Jr., Prof. E. K. Rideal and E. C. Bate Smith, 260

NH, The Band Spectrum of, R. W. Lunt, Dr. R. W. B. Pearse and E. C. W. Smith, 32
NO_2 Molecule, Shape of the, Dr. G. B. B. M. Sutherland and Dr. W. G. Penney, 146
Naga Hills, Agricultural Ceremonies in the, J. P. Mills, 518
Nanga Parbat Adventure: a Himalayan Expedition, F. Bechtold, translated by H. E. G. Tyndale (*Review*), 1005
Natal Museum, Pietermaritzburg, Dr. R. F. Lawrence appointed director of the, 27
Nation, Food and the, 771
National: Institute of Social Science, award of the gold medal of the, to Dr. H. Cushing, 27; Physical Laboratory, Teddington, Inspection by the General Board, 37; Museum of Natural History, Paris: Tercentenary, 77; Central Library, Nineteenth Annual Report of the, 176; Radium Commission, election of members of the, 547; Water Resources, 560; Fruit and Cider Institute and Research Station, Annual Report for 1934, 715; Trust, gift to the, by Viscountess and Dowager Viscountess Rhondda, 830
Natural Philosophy in the Ninth Century, Dr. E. J. Holmyard (*Review*), 889
Nature: Protection of, International Office for the, recognition by the Dutch and French Governments, 178; World of, H. C. Knapp-Fisher (*Review*), 591; Photography and Cinematography, Value of, Earl of Onslow, 675; Recording, New System for, 1023
Naturwissenschaft, Wandlungen in den Grundlagen der, Prof. W. Heisenberg. Zwei Vorträge (*Review*), 322
Naturwissenschaften, Die, Dr. A. Berliner removed from the editorship of, 506
Naval: Architecture in Great Britain [1835], 486; Architects, Institution of: G. V. Boys appointed secretary of the, 677; awards made to H. Lackenby, I. C. Bridge and D. H. Burnett, 730
Nazi-Socialism and International Science, 927
Nebraska, Cultured History in, W. D. Strong, 543
Nebraskan Archæology, Culture Sequence in, W. D. Strong, 555
Nebulæ: Photometry of, P. C. Keenan, 482; Elliptical, Structure of, Sinclair Smith, 877
Nematocysts, Studies of, R. Weill, 232
Nematode in Mice, Life-history of a, B. Schwartz and J. E. Alicata, 150
Nematodes in the Small Intestine of the Sheep, Distribution of, J. H. Tetley, 477
Neolithic Camp in Sussex, 752
Nerve Impulses, Chemical Transmission of, Some implications of the evidence for, Prof. W. B. Cannon, 571
Nervous Mechanism, Knowledge of the, Some recent advances in the, Prof. L. Lapicque, 572
Nests of Mammals, Thermal Adaptation of the, during the growth of the Young, M. Baccino, 449
Neutron Bombardment, Radioactivity of some Rare Earths induced by, late Sir John C. McLennan and W. H. Rann, 831
Neutrons: Slow, Selective Absorption of, J. R. Tillman and Dr. P. B. Moon, 66; with Matter, Interaction of, T. Bjerge and C. H. Westcott; J. R. Dunning, G. B. Pegrum, G. A. Fink and D. P. Mitchell, 557; Slow, Prof. P. Lukirsky and T. Zarewa, 681; Excitation of Nuclei by, W. Ehrenberg, 870; Residual, Absorption of, Dr. L. Szilard, 950; the Slowing Down of, by Collisions with Protons, Dr. H. von Halban, Jr. and Dr. P. Preiswerk, 951; Production of, by Annihilation of Protons and Electrons according to Fermi's Theory, Dr. F. Bloch and Dr. C. Møller, 987; and Gamma-Rays, Chemical Action Caused by, and the Effects

of these Agents on Colloids, Prof. F. L. Hopwood and J. T. Phillips, 1026; Slow, Influence of the Velocity of, on their Capture by Certain Nuclei, Dr. P. Preiswerk and Dr. H. von Halban, Jr., 1027
Nevada: Northern, Geology of, F. C. Schrader, 481; Earthquake of 1934, E. Callaghan and V. P. Gianella, 649
New: York Aquarium, Report of, C. M. Breder, Jr., 99; South Wales, Progress of Correspondence Teaching in, 233; York, Botanical Garden, Dr. M. A. Howe appointed director of the, 333; Zealand: Distribution of Earthquakes in, L. Bastings and R. C. Hayes, 519; Mosses, Vegetative reproduction in, G. O. K. Sainsbury, 526; Seismology in, Dr. C. E. Adams and Dr. J. Henderson, 763; Marlin Swordfishes, Presence of Roes in, V. W. Lindauer, 797; Whitebait, G. Whiteley, 875; Guinea, Explorations in, M. Leahy, 903
"Nicht-Erze", Die wichtigsten Lagerstätten der, Prof. O. Stutzer und Dr. W. Fr. Eppler. Band 6 (*Review*), 815
Nickel: Paramagnetism of, Number of Electrons which contribute to the, L. Néel, 348; -Cobalt Alloys, Structure of the, W. Broniewski and W. Pietrek, 406; and Cobalt, Induced Radioactivity of, J. Rotblat, 515; Oxidisability of, G. Valensi, 693; Steels, Transformation Points of, M. Sauvageot and E. Rousseau, 769
Nigeria, Culture Areas in, W. D. Hambly, 399
Night Sky, Light of the, Lord Rayleigh and Dr. H. Spencer Jones, 688
Nitric Oxide, Magnetic Double Refraction of, H. Bizette and Tsaï Belling, 1001
Nitrogen: and Argon, Solidification of, Prof. P. W. Bridgman, 36; Molecule, Ionisation Potential of the, M. de Hemptinne and J. Savard, 234; Disintegration of, by Neutrons, G. Kirsch and F. Rieder, 350; Monoxide, Disengagement of, during the Decomposition of the Nitrocelluloses, R. Vandoni, 807
Nitrogenous Substances, Structure and Oxidation of, Dr. C. N. Acharya, 644
Nitrous Oxide, Photodissociation of, Prof. P. K. Sen-Gupta, 513
Nobel: Prize for medicine for 1935, award of the, to Prof. H. Spemann, 711; prizes for physics and chemistry for 1935, award of the, to Prof. J. Chadwick and M. and Mme. Joliot-Curie, 824
Nobili, Leopoldo, Death of [1835], 272
Noise: in New York, Campaign against, 753; Conditions of, H. C. Weston and S. Adams, 799
Non: -Cellulosic Constituents from Vegetable Fibres, X-Ray Examination of the Effect of Removing, W. T. Astbury, Dr. R. D. Preston and Dr. A. G. Norman, 391; -Religion of the Future (*Review*), 582
Norfolk Woodhenge, 365
Normandie, Technical features of the, J. Marie, 842
North: Carolina University, Dr. J. A. Wheeler appointed assistant professor of physics, in, 41; East Coast Institution of Engineers and Shipbuilders, Jubilee of the, 60; 129; Sea Bed, Geography of the, R. G. Lewis, 726
Northern: Rhodesia and Katanga, Determination of some Linneites of, by the method of Imprints, T. Hiller, 312; Lights", an Education Film, 507; Rhodesia, Report on a Faunal Survey of, with especial reference to Game, Elephant Control and National Parks, 619
Norway Rat, Inheritance and Linkage Relations of Kinky Coat, A New Mutation in the, A. L. Mitchell, 488
Nova Herculis: and Cosmic Rays, Dr. A. K. Das, 29; Dr. A. Beer, 112; Diurnal variation of Cosmic Ray Intensity and, Dr. J. Barnóthy and Dr. M. Forró, 680
Nuclear: Structure studied *in vivo* by the Method of Ultra-Violet Photography, B. Luyet, 157; Stability, Beta Processes and, Prof. G. Beck, 257; Physics, Lord Rutherford and others, 467
Nuclei, Excitation of, by Neutrons, W. Ehrenberg, 870
Nutrition: and Catering, 691; of Farm Stock, Mechanical Aspect of the, E. J. Sheehy, 963; Study of, 999
Nutritional Response, Relation of Food to Regularity of, H. C. Sherman and H. L. Campbell, 488
Oak, Sisal, Coir and, Molecular Structure in, Dr. E. N. Miles Thomas and J. Hewitt, 69
Observations, Maximum Error of, E. J. Gumbel, 1033
Ocean Depths, Penetrating (*Review*), 586
Odontosyllis phosphorea, Moore, Swarming of, and of other Polychæta near Nanaimo, B.C., E. Berkeley, 1029
Oenothera, 'Luminous' Appearance of, [1835], 806
Œstrogenetic Substances, Chemistry of, E. Friedmann, 108; Prof. J. W. Cook, Prof. E. C. Dodds and F. L. Warren, 912
Ognon, Above Lure (Haute-Saone), Experiment with Fluorescin on the Losses of the, A. Guillerd and E. Bedon, 406
Oil in Great Britain, Production of, 174
Old and New: Thoughts on the Modern Study of History, F. S. Marvin (*Review*), 1009
Olive Oil, Alcoholysis of, Y. Volmar and B. Hansen, 1002
Olivine Basalt—Trachyte Associations, Three, and some Theories of Petrogenesis, B. Edwards, 82
Opaque Minerals, Study of, by the Methods of Impressions, T. Hiller, 312
Open Frame Girder, E. H. Bateman, 866
Optical: Paths, Stationary, Dr. D. S. Kothari, 33; Rotatory Power: Theory of, Prof. Max Born, 191; Origin of, Prof. T. M. Lowry, 191; Activity, A Landmark in the Study of, Prof. T. A. Patterson (*Review*), 454; Rotatory Power, Prof. T. M. Lowry (*Review*), 454; Instruments, Vision in (Thomas Young oration), Prof. C. Fabry, 946
Orchids, Tropical, Hybrids of, J. Costantin, 993
Ordnance Survey Maps, Scales of, 984
Ordovician Submarine Disturbances in the Girvan District, S. M. K. Henderson, 196
Organic: Synthesis, Unit Processes in, P. H. Groggins, Editor-in-Chief (*Review*), 8; Oxides, Dissociable, C. Dufraisse and A. Etienne, 448; Soils and Epinastic Response, Prof. W. Neilson Jones, 554; Oxides, Dissociable, and the Anthracene Structure, C. Dufraisse and M. Gérard, 563; Syntheses, C. R. Noller, Editor-in-Chief. Vol. 15 (*Review*), 592
"Origin (and Development) of Species", A Postscript upon the, E. Heron-Allen, 132
Orissā: the Hill Bhūiyās of, with Comparative Notes on the Plains Bhūiyās, S. C. Roy (*Review*), 591
Ornithological Progress During the Past Fifty Years, Rev. F. C. R. Jourdain, 155
Ornithorhynchus, Dentition of, Dr. R. Broom, 219
Ostracods, Freshwater, Sperms of A. G. Lowndes, 610
"Outline", A New (*Review*), 851
Ovada Disaster, the, 291
Oxford: Physiologists: Two, a Bibliography of, Richard Lower, 1631–1691, John Mayow, 1643–1679, Prof. J. F. Fulton (*Review*), 702; University: resignation of Sir Charles Sherrington; D. Roaf elected Duke of Westminster research student at Christ Church; J. A. Moy Thomas elected a lecturer in vertebrate palæontology at Christ Church; E. W. Yemm elected a junior research fellow in botany at Queen's College, 41; gift by Lord Nuffield; Prof. P. M. S. Blackett appointed Halley lecturer for 1936 and Prof. J. A. Smith appointed Herbert Spencer lecturer for 1936; award of the Osler memorial medal to Dr. A. F. Hurst, 79; Prof. H. S. Jennings appointed George Eastman visiting professor and fellow of Balliol College; Prof. G. H. Hardy elected an honorary fellow of New College; B. V. Rollin and G. J. Whitrow elected Harmsworth senior scholars at Merton College, 654; Dr. J. G. Priestley appointed deputy for the professor of physiology; Dr. F. G. Hobson appointed Litchfield lecturer in medicine, H. A. B. Whitelocke Litchfield lecturer in surgery, Dr. J. Marschak director of the Institute of Statistics and Dr. L. H. D. Buxton reader in physical anthropology, 692; Prof. J. Mellanby appointed Waynflete professor of physiology, 730; title of professor granted to H. Balfour; scientific contributions of members of New and All Souls Colleges, Dr. R. T. Gunther, 805; Early Men of Science of Magdalen College, Dr. R. T. Gunther, 881; use by the museum of the history of science of the Old Ashmolean building, 923

Oxidation, Biological, Chemical Aspects of, Prof. N. R. Dhar, 36
Oxide: Film of Alloys Containing Small Percentages of Aluminium, I. Iitaka and S. Miyake, 437; Nitrous, Photodissociation of, Prof. P. K. Sen-Gupta, 513
Oxygen: in the Sun's Chromosphere, T. Royds, 606; Solid, Structure of, Prof. L. Vegard, 720; Isotopes, Electrolytic Separation of the, G. Ogden, 912
Oyster Culture in Norway, T. Gaarder and P. Bjerkan, 228
Ozone: Absorption Spectrum of, in the Region of the Photographic Infra-Red, Mme. Lucie Lefebvre, 43; Thermal Decomposition of, Dr. M. Ritchie, 221; Atmospheric, Determination of, A. Dauvillier, 807; Maximum Concentration of, and of Nitric Oxide at High Temperatures of Endothermic Bodies, E. Briner, B. Susz and E. Rod, 1039

Pacific: Entomological Survey, 35; Surface Structure beneath the, H. F. Baird, 723; Dr. R. Stoneley, 990
Pain and its Physiological Effects, Prof. L. A. Orbeli, 572
Palæozoic Sediments near Burgonia, G. F. K. Naylor, 845
Paläographie: mit besonderer Rücksicht auf die Fehlerquellen, Dr. F. Kerner-Marilaun (*Review*), 166
Palestine: and Trans-Jordan, The Handbook of, Edited by Sir Harry Luke and E. Keith-Roach. Third edition (*Review*), 166; Electric Progress in, Lord Reading, 544; Early Man in, Miss D. A. E. Garrod; Sir Arthur Keith; T. D. McCown, 610
Palladium: and Gold, Isotopic Constitution of, Prof. A. J. Dempster, 65; Large and Sudden Variation in the Permeability of, to Hydrogen at a Temperature just below 200° C., V. Lombard and C. Eichner, 81
Pantothenic Acid and the Nodule Bacteria-Legume Symbiosis, C. H. McBurney, W. B. Bollen and R. J. Williams, 407
Papua: Northern, Exploration in, 251; Unknown, 290
Para-Azoxyanisol, Viscosity of, Influence of a Magnetic Field on the, M. Miesowicz, 261
Parasitism and Disease, late Prof. Theobald Smith (*Review*), 738
Parexocœtus, a Red Sea Flying Fish in the Mediterranean, A. F. Bruun, 553
Paris to St. Germain Railway [1835], 768
Parliamentary Science Committee, election of officers, 945
Paschen-Back Effect, Measurements of the, with the Bellevue Electromagnet Fitted with Supplementary Coils, P. Jacquinot and T. Belling, 883
Passivity Phenomena, Theory of, W. J. Müller and O. Hering (27), 235
Pasteur: a bust of, unveiled at Havana, 678; Institute, Kasauli, Thirty-third Annual Report, 677
Pasture Research within the Empire, Prof. R. G. Stapledon and others, 402
Pasteurization of Milk, Sir Arnold Wilson and others, 1
Pavement Widths, Effect of, upon Accidents, Prof. R. L. Morrison, 561
Peace, Safeguarding of, 576
Pearl Organs in Fishes, Dr. Y. Okada, 228
Pedersen, Prof. P. O., papers in commemoration of the sixtieth birthday of, 294
Peking Man, Food of, Dr. R. W. Chaney, 577
Penetration, Kinetics of, A. G. Jacques (10), 488
Periodicity: Shifting of, by Means of High Temperatures, Miss A. M. Hartsema and A. H. Blaauw, 617; Study of, J. Legrand, 693
Permian Insect Fossils, New Discoveries of, Prof. A. G. Martynov, 294
Personality and Age, Dr. Ll. Wynn Jones, 385; 779
Perspiration and Erythema, Prof. W. H. Crew, 340
Peru, Proposed Establishment of a Serological Institute in, 27
Petroleum: Industry of France, V. Forbin, 40; Fuels in Canada, 73; in Bulk, Ocean Transportation of, R. F. Hand, 255; and Tar Oils as Insecticides, Dr. H. Martin, 676; Refinery Operations, Costing of, G. Kerr, 839
Pflanze, Paläohistologie der, Dr. Elise Hofmann (*Review*), 891
Pflanzenanatomie, Handbuch der, Herausgegeben von Prof. K. Linsbauer. Allgemeiner Teil: Cytologie (Die Organe der Zelle) Band 2: Allgemeine Pflanzenkaryologie. Hälfte 1: Der "Ruhekern", Prof. G. Tischler. Zweite auflage (*Review*), 495
Pflanzengeographie auf physiologischer Grundlage, Prof. A. F. W. Schimper. Dritte auflage, herausgegeben von Prof. F. C. von Faber. Band 1 und 2 (*Review*), 587
Phalaris canariensis, Nutritive Value of, F. Rogozinski and Z. Glowczynski, 158
Phase Diagrams, Principles of, J. S. Marsh (*Review*), 598
Phenol and Aniline, a New Compound of, P. Laurent, 731
Philippine Islands, Fishes from the, D. V. Villadolid and P. R. Manacop; M. C. and H. R. Montalban, 440
Philosophical and Natural Sciences as taught in Baghdad about A.D. 817, or Book of Treasures, Encyclopædia of, Job of Edessa. Syriac text edited and translated with a critical apparatus by Dr. A. Mingana (*Review*), 889
Philosophy: and Modern Science, Dr. H. Jeffreys; Prof. H. Levy, 106; Prof. G. Dawes Hicks, 183; Dr. H. Jeffreys, 261; The Problem in, R. H. S. Crossman, 118; Science and (*Review*), 239; Twenty-five Years of, 332
Phloridzin, Inhibitory Effect of, on an Enzymic Dismutation, H. Kalckar, 872
Phonemes, Prof. E. W. Scripture, 261; 644; W. F. Twaddell, 644
Phonetics, Experimental, and Ancient Greek Verse, Prof. E. W. Scripture, 340
Phosphate in the Western Basin of the North Atlantic, H. R. Seiwell, 206
Phosphatide Autocomplex Coacervates as Ionic Systems and their Relation to the Protoplasmic Membrane, H. G. Bungenberg de Jong and J. Bonner, 617
Phosphorus Metabolism in Rats, Radioactive Indicators in the Study of, O. Chiewitz and Prof. G. Hevesy, 754
Photocell, the Rectifier, G. P. Barnard, 74
Photochemical Reactions Connected with the Quenching of Fluorescence of Dyestuffs by Ferrous Ions in Solution, Dr. J. Weiss, 794
Photo-Elastic Laboratory, Equipment of a, Prof. E. G. Coker, 136
Photoelectricity and Surface Chemistry, J. S. Wilson (*Review*), 589
Photographic: Lens, Development of the, W. Taylor and H. W. Lee, 190; Emulsions, Ray Tracks in, H. J. Taylor, 306; Films, Desensitised, Sensitiveness of, in Dependence on Atmospheric Oxygen and on the Concentration of the Desensitiser, Marietta Blau and Hertha Wambacher, 407; Photometry, an Error in, J. Lagrula, 1038; Plates, Chromatic Sensibility of Ordinary, Analytical Representation of the, P. Rossier, 1039
Photography, Stereoscopic, a Note on, Dr. J. R. Baker, 193
Photométrique, Encyclopédia, Quatrième section: Cas extrêmes. Tome 4. Marguerite Moreau-Hanot (*Review*), 773
Photosynthesis: the Rate of, Dr. W. O. James, 220; Kinetics of, Prof. E. C. C. Baly, 34
Phycomyces, Nitrogenous Metabolism of the, Role of Vitamin B in the, W. H. Schopfer, 273
Physical: Society, The, Reports on Progress in Physics (*Review*), 49; Reality, Quantum Mechanics and, Prof. N. Bohr, 65; Units and their Dimensions, Sir Joseph Larmor, 548; Science, Symbols and Nomenclature in, 840
Physicists, Industrial, Training for, 254
Physics: International Conference on, London, 1934. 2 Vols. Reports on Symbols, Units and Nomenclature (*Review*), 49; Progress of (*Review*), 49; in Chemistry (*Review*), 125; Intermediate, Dr. C. J. Smith. Second edition (*Review*), 205; Modern, Philosophy of (*Review*), 354; Nuclear, Lord Ruther-

ford and others, 467; Theoretical, Prof. G. Joos. Translated by Dr. I. M. Freeman (*Review*), 495; the New, Sir William Bragg (Sir Halley Stewart Trust lecture), 711; A Source Book in, Prof. W. F. Magie (*Review*), 773; Original Sources in (*Review*), 773; Institute of, Prof. S. W. J. Smith elected chairman of the Midland Local Section of the, 830; in Industry in the United States, 946; for College Students, an Introduction to the Study of the Physical Sciences, Prof. A. A. Knowlton. Second edition (*Review*), 972; Modern, French Pamphlets on, 982

Physik: Handbuch der, Herausgegeben von H. Geiger und K. Scheel. Zweite auflage. Band 23, Teil 2: Röntgenstrahlung: Ausschliesslich Röntgenoptik, Redigiert von H. Geiger (*Review*), 279; theoretischen, Lehrbuch der, Prof. G. Joos. Zweite auflage (*Review*), 495

Physiological: Congress, International, Fifteenth, Dr. D. Y. Solandt, 571; Processes, Velocities of Some, Sir Joseph Barcroft, 572; Lability and the Act of Inhibition, Prof. A. A. Ukhtomsky, 573; Congresses, Permanent International Committee of the, election of new members, 573; 640; 1024

Physiology, French Monographs of, 63

Phytocarcinomata, Ascorbic Acid (Vitamin C) and, L. Havas, 989

Phytoplankton: and the Herring, Part 1, R. E. Savage and Prof. A. C. Hardy, 962; of Table Bay, Variation in the, October 1934–October 1935, with a Note on the Technical Analysis of *Chaetoceras*, W. J. Copenhagen, 1039

Picric Acid in the *p*H Scale, the Physicochemical Properties of, J. Molnar, 311

Piles and Pile Driving, A. C. Dean (*Review*), 593

(*Pilocarpus*), Alkaloids of the Leaves of Jaborandi, N. A. and V. A. Predbrazhenskij (7), 1040

Pineapple, The, M. O. Johnson (*Review*), 533

Pine Forests: Utilisation of, Cellulose Pulp, 1014

Pinene, Pyrolysis of, G. Dupont and R. Dulou, 406

Pinus, Leaf and Scale Types in, Dr. C. C. Doak, 958

Pithecanthropus and the Gibbon, Dr. E. Dubois, 838

Pitt-Rivers Museum, Oxford, Prof. H. Balfour and the, 861

Pituitary Gland, The, Prof. P. T. Herring, 385

Place-Names: of Essex, the, P. H. Reaney (*Review*), 736; Scientific Study of (*Review*), 737

Planets, Atmospheres of the, C. Piccardi, 564

Plankton Production and the Nitrate Nitrogen and Phosphate Cycles in the Pacific Ocean off New South Wales, Prof. W. J. Dakin and A. N. Colefax, 339

Plantes alimentaires chez tous les peuples et à travers les âges: les, Histoire, utilisation, culture, Prof. D. Bois. Vol. 3 (*Review*), 663

Plant: Virus Diseases, Experiments on, Dr. J. Caldwell, 343; Pathology, F. T. Brooks, 386; Virus Infection, the Problem of a, Dr. Kenneth M. Smith, 395; Pathology: Some Aspects of, F. T. Brooks, 462; Problems of, 462; Metabolism, Zinc and, Prof. W. Neilson Jones, 646; Nutrition, Role of Organic Matter in, Subrahmanyan and others, 876; Lipochrome, a New Type of, Prof. I. M. Heilbron, B. Lythgoe and R. F. Phipers, 989

Plastic Bodies, Rupture of, Influence of Viscosity Variation on the, Dr. R. K. Schofield and G. W. S. Blair, 147

Platinum: Isotopes and their Nuclear Spin, Prof. B. Venkatesachar and L. Sibaiya, 65; Compounds, Structure of, W. H. Mills and T. H. H. Quibell, 151; Electrode in Solutions of Foreign Ions, I. Orestov, 442

Plato's Theory of Knowledge: the *Theaetetus* and the *Sophist* of Plato translated with a running commentary, Prof. F. M. Cornford (*Review*), 777

Plenty: Economics of, 809; The Calculus of, Sir Josiah Stamp (Norman Lockyer lecture), 809

Pleochroism of Crystals of Rare-Earth Salts as Evidence of the Non-rotation of Certain Electronic Orbits, Dr. E. E. Jelley, 335

Pleuropneumonia, Organism of, Life-history of the, A. W. Turner, 555

Plexauridæ, The Gorgonid Family, Dr. G. Stiasny, 304

Podogona (Ricinulei), Rarity of the Archaic Arachnids Dr. Susan Finnegan, 186

Poison Gas, A. Marshall, 170

Poisons List and Poison Rules, the Draft, 247

'Pola Filter', the, Eastman Kodak Company, 136

Poland, Nature Protection in, 752

Polar Regions, Some Aspects of the, Prof. F. Debenham, 382; 459

Polish Science in the Middle Ages, 368

Political: Responsibility, Science and, 733; Education, an Experiment in, Dr. J. W. Studebaker, 749

Polonium α-Rays, Disintegrability of the Elements from Argon to Manganese by, J. Schintlmeister and E. Föyn, 407

Polymerisation and Condensation Reactions, Prof. E. K. Rideal, 626

Polynesian Crustacea, New and Rare, C. H. Edmondson, 343

Port Erin, Marine Research at, 331

Porto Rico and the Virgin Islands, Scientific Survey of, W. L. Schmitt; C. R. Shoemaker, 188

Positrons: Emission of, from a Thorium-Active Deposit, Prof. A. I. Alichanow, A. I. Alichanian and M. S. Kosodaew, 475; from Radioactive Sources, Emission of, Prof. A. I. Alichanow, A. I. Alichanian and M. S. Kosodaew, 719

Post Office: Publicity, 137; the Press and the, J. H. Brebner, 828

Potash-rich Rocks, Origin of, Ruth Doggett Terzaghi, 688

Potassium: in the Presence of Sodium, Gravimetric Micro-estimation of, by means of Chlorplatinic Acid, C. Cimmermann and C. Rzymowska, 81; Chloride, Heat Capacity of, from 2·3° to 17° K., Prof. W. H. Keesom and C. W. Clark, 235; Lactate, Expansion of Films of Myosin on, S. A. Moss, Jr., Prof. E. K. Rideal and E. C. Bate Smith, 260; Radioactivity of, Dr. K. Sitte, 334; Iodide, Antagonistic Effect of, in Baldness due to Thallium Acetate, O. V. Hykeš and F. A. Diakov, 685; Radioactivity of, $_{19}K^{43}$ and the, H. J. Walke, 755

Potato: in the Mountainous Regions of Morocco, Indigenous Cultivation of the, E. Miège, 81; Influence of Cold on the Conservation and Productivity of the, E. Miège, 119

Potatoes in Victoria, Brown Rot Disease of, B. J. Grieve, 883

Potlatch and Totem: and the Recollections of an Indian Agent, W. M. Halliday (*Review*), 934

Power Output Valve, A New, J. H. O. Harries, 267

Pre- and Protohistoric Sciences, International Congress of, 428

Precision Gauges for Interchangeability, Principle and Design of, R. J. Foster, 18

Prehistoric: Archæology and Sir Ray Lankester, J. Reid Moir (*Review*), 356; Copper and Bronze, Dr. Plenderleith, 724

Pre-Medical Studies, the Schools and, Dr. G. R. de Beer; W. J. R. D., 874

Primordial Ocean: The, an Introductory Contribution to Social Psychology, Dr. W. J. Perry (*Review*), 581

Princeton University, Prof. R. H. Fowler appointed visiting lecturer in mathematics at, 140

Probability: The Meaning of, Dr. H. Dingle, 423; and Frequency, F. P. Cantelli, 442; the Meaning of, W. Barrett; T. Smith; Dr. H. Dingle, 604

Proboscidea, Ancestral Tree of the, Prof. H. F. Osborn, 408

'Pro-Knocks' and Hydrocarbon Combustion, A. R. Ubbelohde, J. W. Drinkwater and A. Egerton, 882

n-Propyl Radical, the Free, Dr. T. G. Pearson and Dr. R. H. Purcell, 221

Prosperity, Organizing, Mr. Lloyd George, 174

Prosthetic Group of Catalase, Constitution of the, Dr. K. G. Stern, 302

Protactinium with Titanium, Co-precipitation of, Mlle. H. Zavizziano, 80

Protease ? Do Bacteria Secrete, W. Moycho, 925
Protective Colour Change, F. B. Sumner (3), 408
Protein : in Animals, Specific Dynamic Action of, Correlation between Excess Calories and Excess Urinary Nitrogen in the, H. Borsook, 488 ; Thioderivatives, Formation of, with the Aid of Carbon Disulphide, J. Loiseleur, 1002
Proton, Mass of the, Quantised Field Theory and the, Dr. Max Born, 952
Protons and Neutrons, Theory of, G. Wataghin, 731
Prussian Academy of Sciences, Prof. F. O. Bower elected a corresponding member of the, 908
Psychical Research, Short-Title Catalogue of Works on, H. Price, 293
Psychodiagnosis, Development Test as Applied to Infants in the Service of, Hildegarde Hetzer and Anneliese Braun, 762
Psychologique, L'Année, Publiée par Prof. H. Piéron. Année 34 (1933). 2 Vols. (*Review*), 597
Psychology : The Frontiers of, Prof. W. McDougall (*Review*), 239 ; and Health, Dr. H. Banister (*Review*), 319 ; and Religion, Dr. D. Forsyth (*Review*), 582 ; Wants, Interests and Attitudes, Prof. E. L. Thorndike and others (*Review*), 585
Public Relations Work ? Whither, Dr. W. A. Hamor, 366
Puerto Rico, Tropical Diseases Research in, 332
Punched Card Method in Colleges and Universities, Practical Applications of the, Edited by G. W. Baehne (*Review*), 415
Purine Derivatives, Thermal Data for, R. D. Stiehler and H. M. Huffman, 801
Pyrethrines, Comparative Toxicity of the, Towards Different Classes of Animals, O. Gaudin, 487
Pyridine, Raman Spectrum of, Relation between the Ultra-violet Absorption Spectrum and the, V. Henri and P. Argenot, 964
Pyrocydonia Winkleri, Hydrocyanic Acid in, M. Cormier, 157

Quadratic Wave Equation : Flood Waves in a Channel with Quadratic Friction, M. A. Biot, 488
Quantitative Analysis, Concentration Cell in, N. H. Furman and G. W. Low, 920
Quantum : Mechanics and Physical Reality, Prof. N. Bohr, 65 ; Theory, the Fundamental Paradox of the, H. Fröhlich and E. Guth ; Prof. G. Temple, 179 ; Dr. R. Peierls, 395 ; Mechanics, The Principles of, Prof. P. A. M. Dirac. Second edition (*Review*), 411 ; Theory, The (*Review*), 411 ; Mechanics : Introduction to, with Applications to Chemistry, Prof. L. Pauling and Dr. E. B. Wilson, 972 ; Theory, Geometry and Relativity, T. Hosokawa ; K. Morinaga, T. Sibata, Y. Mimura ; T. Iwatsuki, 994
Quartz, Rotatory Power of, for Rays Perpendicular to the Optic Axis and its Dispersion between 2537A. and 5780A., G. Bruhat and L. Weil, 964
Quetta Earthquake of May 31, 331
Quimica e Farmacia, Revista de, No. 1, 908
Quinine Sulphate, Radiation Accompanying the Dehydration of, M. Prost, 349
p-Quinone and Related Compounds, Electrical Moments of, D. Ll. Hammick, G. C. Hampson and G. I. Jenkins, 990

Rabbit Menace in Australia in 1933 and the Way Out, D. G. Stead, 430
Rabbits, Rickets in, Incidence of, W. K. Wilson, 434
Rabic Marrows, Virulence of, Comparative Action of Immersion in Glycerol and of Freezing on the Preservation of the, P. Lépine, 349
Rabies in South Africa, 63
Race and Culture Contacts, Edited by Prof. E. B. Reuter (*Review*), 584
Racial Myth, The, C. Dover (*Review*), 736
Radiation : from Transmitting Aerial, 270 ; from a Vertical Antenna over Flat Perfectly Conducting Earth, Prof. P. O. Pedersen, 270
Radioactive : Elements, Beta Ray Spectra of Artificially Produced, Prof. A. I. Alichanow, A. I. Alichanian and B. S. Dželepow, 257 ; Indicators in the Study of Phosphorus Metabolism in Rats, O. Chiewitz and Prof. G. Hevesy, 754
Radioactivity : Artificial : of the Rare Earth Elements, Dr. J. K. Marsh and Prof. S. Sugden, 102 ; of Dysprosium and other Rare Earth Elements, Prof. G. Hevesy and Miss Hilde Levi, 103 ; Progress in the Production of, Prof. E. Lawrence, 329 ; of Potassium, Dr. K. Sitte, 334 ; Induced, by Bombarding Magnesium with α-Particles, Dr. C. D. Ellis and W. J. Henderson, 755 ; of Potassium, $_{19}K^{42}$ and the, H. J. Walke, 755 ; of Some Rare Earths Induced by Neutron Bombardment, late Sir John C. McLennan and W. H. Rann, 831 ; of Ferro-Manganese Formations in Seas and Lakes of the U.S.S.R., L. M. Kurbatov, 871 ; of Oil-waters in Czechoslovakia, Prof. F. Běhounek, V. Santholzer and Prof. F. Ulrich, 910
Radio : -Elements, Artificial, Deposition of, by Electrochemical Exchange, M. Haissinsky, 141 ; Broadcasting in India, Development of Nation-wide, K. Sreenivasan, 231 ; Exhibition at Olympia, The, 308 ; Stations, Synchronisation of, 429 ; Research in Australia, 650 ; -Elements Produced by Neutrons, Some, P. Preiswerk and H. von Halban, Jr., 844 ; Research Laboratories Abroad, 905 ; Transmission, Solar Activity and, 947 ; Beacon, a Method of Improving the, H. A. Thomas, 959 ; Data Charts, Dr. R. T. Beatty. Second edition, 983
Radiography, Industrial, Dr. A. St. John and H. R. Isenburger (*Review*), 279
Radiology : British Institute of, Annual Congress and Exhibition, 960 ; Forty Years of (1895–1935), Dr. G. W. C. Kaye (Silvanus Thompson memorial lecture), 960
Radium : Deposits in North-West Canada, Dr. H. S. Spence, 510 ; for research, gift to Prof. N. Bohr, 602
Radon Content, Momentary, of the Open Air at Spas with Radioactive Waters, Measuring the, W. Kosmath, 44
Railway Electrification, Prof. H. Parodi, 366
'Rain-frog' of China, Ju-chi Li and Chang-shan Lin, 724
Raman : Spectra : of HSD and ND_3, A. Dadieu and H. Kopper, 235 ; of SeH_2, SeD_2 and SeDH, A. Dadieu and W. Engler, 235 ; Effect in Solutions of Some Amino Acids, N. Wright and W. C. Lee, 300 ; Spectrum of $CDCL_2$, A. Dadieu and W. Engler, 407 ; Effect (45), K. W. F. Kohlrausch and G. P. Ypsilanti, 450 ; Spectra of Benzenepolycarboxylic Esters, A. Pongratz and R. Seka, 450 ; Spectrum : of Heavy Water, R. Ananthakrishnan, 551 ; of Nitric Anhydride, J. Chédin, 731 ; of Liquid Heavy Water, E. Bauer and M. Magat, 807 ; Effect in Fuming Sulphuric Acid, J. Chédin, 844 ; Spectrum of Heavy and Light Phosphoretted Hydrogen, M. de Hemptinne and J. M. Delfosse, 845
Rana catesbeiana, Shaw, Food of, S. W. Frost, 983
(*Ranzania*), the Oblong Sunfish, in the Indian Ocean, G. P. Whitley, 338
Rare Earth Elements : Artificial Radioactivity of the, Dr. J. K. Marsh and Prof. S. Sugden, 102 ; Dysprosium and other, Artificial Radioactivity of, Prof. G. Hevesy and Miss Hilde Levi, 103
Rassenkund und ihre Nachbargebiete, Zeitschrift für, 577
Rat, Male, Sexual Organs of the, Activity of Androstendione on the, Dr. E. Tschopp, 258
(*Rattus norvegicus*), Linkage Studies of the Rat, Helen Dean King and W. E. Castle, 408
Rayleigh Line in Liquids, Origin of the Wing Accompanying the, Dr. S. C. Sirkar, 759
Rayons X : Les, au laboratoire, à l'hôpital, à l'usine, M. Privault (*Review*), 279
Reaction Velocity and Thermodynamics, Prof. M. Polanyi, 17
Reading University, conferment of honorary doctorates on Sir Rowland Biffen, Sir Frederick Gowland Hopkins, Lord Rutherford and Sir J. J. Thomson ; gift to, by R. Marden, 923

Recession, Spiral Orbits and the Law of, Dr. V. V. Narlikar and K. V. Sastry, 515
Recrystallisation accompanying an Allotropic Change, Dr. C. F. Elam, 917
Rectifiers, Steel Tank, Operating on the Underground Railways, A. L. Lunn, 864
Red: Currant, a Disease-Resistant, Dr. G. G. Hahn, 176; Clover, Development of, Effect of Pressure of Atmosphere on, Prof. P. W. Wilson, 262; Kafirs of Nuristan, 330
Refractive Index in Liquid Media, Making Evident Small Differences of the, A. Magnan and C. Magnan, 1001
Refrigeration Hygrometry, J. H. Awbery and Dr. E. Griffiths, 229
Regional Magnetic Survey, A, E. H. Booth, 273
Registrar-General's Statistical Review of 1934, Tables (Medical) of the, 713
Relativity: an Elementary Explanation of the Space-time Relations as Established by Minkowski, and a Discussion of Gravitational Theory Based Thereon, Dr. F. W. Lanchester (*Review*), 621
Religion, The Origins of, Prof. R. Karsten (*Review*), 357
Reptiles of the World: the Crocodilians, Lizards, Snakes, Turtles and Tortoises of the Eastern and Western Hemispheres, Dr. R. L. Ditmars. New edition (*Review*), 529
Research: the Pathfinder of Science and Industry, T. A. Boyd (*Review*), 244
Resorcinol, a Molecular Map of, Dr. J. M. Robertson, 755
Respirators, Civilian, 252
Retina, the Metabolism of, Dr. H. Laser, 184
Rhodesia, Southern, Meteorology of, 751
Rhododendron White Fly, G. Fox Wilson, 343
Rhyolite *coulée*, Radiometric Exploration of a, E. Rothé and Mme. A. Hée, 964
Rickets in Rabbits, Incidence of, W. K. Wilson, 434
Ring Deposits on Glass by Positive Ray Bombardment, Prof. B. Dasannacharya, V. T. Chiplonkar and L. G. Sapre, 642
Road: Signals, Traffic-actuated, F. Edwards, 253; Width and Accidents, 561; Traffic, Scientific Control of, A. T. V. Robinson, 578; Accidents, the Psychological Approach to the Problem of, Dr. C. S. Myers, 740; Research, Progress in, 841
Rockefeller: Medical Fellowships, awards to Prof. D. F. Anderson, N. R. Barrett, A. C. P. Campbell, D. H. K. Lee, J. E. A. O'Connell and R. Walmsley, 64; Institute, New York, Dr. W. A. Sawyer appointed director of the Division of International Health of the, 949; Dr. H. S. Gassen nominated director of the, 1024
Rocks, the Herbarium of the, Prof. A. C. Seward, 155
Roes in New Zealand Marlin Swordfishes, Presence of, V. W. Lindauer, 797
Roman: Fort at Brough, P. Corder, 34; Yorkshire, Investigation of, 674
Romanticism and the Modern World, F. L. Lucas, 944
Röntgenspektrographie als Untersuchungsmethode bei Hochmolekularen Substanzen, bei Kolloiden und bei tierischen und pflanzenlichen Geweben, Die, Dr. J. R. Katz (*Review*), 1006
Rose Seeds, After-ripening and Germination of, Dr. M. A. H. Tincker, 349
Rothamsted Experimental Station, Report for 1934, 521
Royal: College of Physicians: of London, awards of the, 178; presentation of the Baly gold medal to Dr. F. H. A. Marshall and of the Bisset-Hawkins gold medal to Sir George Newman, 678; Institution: Dr. E. Mellanby elected Fullerian professor of physiology at the, 27; A. R. Ubbelohde awarded the Dewar research fellowship, 256; H. Brown's legacy, 825; reconstruction of the library, 826; Meteorological Society, award of the Symons gold medal to Prof. W. Schmidt, 867; Photographic Society, Annual Exhibition, 523; Physiological Society of Lund, Prof. F. G. Donnan elected a foreign member of the chemistry division of the, 830; Society: election as foreign members of, Dr. I. Langmuir and Prof. Max Carl Wilhelm Weber, 14; award of the Mackinnon research studentship to Dr. G. W. Brindley, 753; award of Royal medals to Prof. C. G. Darwin and Dr. A. Harker, the Copley medal to Prof. C. T. R. Wilson, the Davy medal to Prof. A. Harden and the Hughes medal to Dr. C. J. Davisson, 824; election of officers, 824; meeting of the, [1835], 843; anniversary meeting, [1835], 882; of Arts, presentation of the Albert medal to Sir Robert Hadfield, Bt., 58; of Canada, annual meeting; presentation of the Flavelle medal to Dr. F. T. Shutt; award of the Lorne Pierce medal to Dr. E. Montpetit and the Tyrrell medal to Brig.-Genl. E. A. Cruikshank, 326; of Edinburgh: election of Prof. R. Anschütz as a foreign honorary fellow of the, 27; election of officers, 715; award of the David Anderson-Berry prize to Dr. C. M. Scott, 716; Asiatic Society, conferment upon Prof. W. Geiger of the honorary membership of the, 949; College of Physicians of Edinburgh, Laboratory of the, Report for 1934, 1023; Geographical Society, meeting of the, [1835], 963; Horticultural Society, awards of the, 1024; Society: election of officers, 902; Anniversary meeting of the, 921; of Canada, Dr. G. A. Young elected president, 985
Rubber: The Science of ("Handbuch der Kautschukwissenschaft"), edited by Prof. K. Memmler. English translation, edited by Dr. R. F. Dunbrook and Dr. V. N. Morris (*Review*), 321; Yield, Prediction of, H. Gunnery, 800; a Toxic Emanation from, Dr. K. Mellanby and Dr. P. A. Buxton, 873
Rural Young Folk, Interests, Activities and Problems of, W. A. Anderson and W. Kerns (2), 838
Rusting Iron, the Electric Currents flowing over, Dr. U. R. Evans, 792

SeO and SeO_2, Spectra of, Dr. R. K. Asundi, M. Jan-Khan and Prof. R. Samuel, 642
'Sabbatical Year' for University Teachers, Plea for a, G. F. H. Harker, 156
St. Andrews University: foundation by Mrs. Low of a "Capt. W. A. Low memorial prize"; Dr. J. A. Macdonald appointed a lecturer in botany in the United College; Dr. A. B. Stewart appointed lecturer in bacteriology in the Dundee Medical School; Dr. E. T. Copson inducted professor of mathematics and Dr. R. C. Garry professor of physiology in Dundee University College, 615; R. C. Alexander appointed professor of surgery, 881
Sahara, Encroachment of the, Prof. E. P. Stebbing, 112; 1036
Salamander, the Anatomy of the, Dr. E. T. B. Francis. With an historical introduction by Prof. F. J. Cole (*Review*), 87
Salivary Gland, the Chromosome Micelle and the Banded Structure of Chromosomes in the, Dr. Dorothy M. Wrinch, 68
Salt: on Clay, Effect of, Prof. H. Ries, 482; -Marsh, Ecology of a, Edith A. T. Nicol, 838; Absorption by Plant Cells, Mechanism of, Dr. W. J. V. Osterhout, 1034; Dr. F. C. Steward, 1035
Salts, Transport Numbers of, L. G. Longsworth, 344
Samarium, Radioactivity of, Prof. H. J. Taylor, 719
Samoa, Insects of, 217; Prof. P. A. Buxton, 343
Sanāq: Das Giftbuch des, eine Literaturgeschichtliche Untersuchung, Bettina Strauss (*Review*), 128
San Diego Natural History, 579
Sandjak Waters, Dissolved Salts in the, V. Frolow, 769
Saturated Fatty Alcohols and Ethylene Hydrocarbons, Diffusion Spectra (Raman Effect) and Infra-Red Absorption Spectra of, A. Andant, P. Lambert and J. Lecomte, 525
Sawflies, a New Family of, and the Genera of the Cephidæ, R. B. Benson, 992
St. Thomas's Hospital, Anatomy Department of, 827
Scent and the Weather, Lieut.-Col. C. J. R. Turner, 60
Schardinger Enzyme Preparations, Oxidative Inactivation of Co-zymase with, Dr. F. Lipmann, 913
Schmidt and the Eels: Danish Eel Investigations during Twenty-five Years, 820

School: Dietaries, Prof. H. E. Armstrong, 749; and Museum in London Education, 787
Schools, the, and Pre-Medical Studies, 706; Dr. G. R. de Beer; W. J. R. D., 874
Science: Modern, the Foundations of, Sir William Dampier (*Review*), 85; Museum: Harrison's Chronometers at the, 216; Report of the, for 1934, 255; Air Transport Exhibition at the, 863; News a Century ago, 41; 79; 118; 156; 195; 272; 310; 348; 405; 447; 562; 486; 524; 616; 654; 693; 730; 768; 806; 843; 882; 923; 963; 1000; Service in London, A, 542; Technology and Philosophy in the 16th and 17th Centuries, A History of, Prof. A. Wolf, with the Co-operation of Prof. F. Dannemann and A. Armitage (*Review*), 85; Modern, Philosophy and, Dr. H. Jeffreys; Prof. H. Levy, 106; the Dissemination of, Watson Davis, 176; Modern Philosophy and, Prof. G. Dawes Hicks, 183; and Culture, Part 1, 214; and Philosophy (*Review*), 239; Modern, Philosophy and, Dr. H. Jeffreys, 261; and Leadership in Industry, 313; and the Human Temperament, Prof. E. Schrödinger. Translated, and with a biographical introduction, by Dr. J. Murphy; ditto, Translated by Dr. J. Murphy and W. H. Johnston (*Review*), 354; Social, 409; and Population Problems, Sir Arnold Wilson, 427; Interpretation of, Sir Richard Gregory, Bt., 558; and the Public Mind, Dr. B. C. Gruenberg (*Review*), 583; the Interpretation of, R. Brightman (*Review*), 583; in the Making, G. Heard (*Review*), 583; Forthcoming Books of, 599; and Political Responsibility, 733; A New Outline, J. W. N. Sullivan (*Review*), 851; Exploitation of, in Company Promotion, 861; and Social Needs, Prof. J. S. Huxley (Sir Halley Stewart Trust lecture, 865; Everyday, in Civil Service Examinations, Dr. H. Dingle, 866; Humanistic, 885; and the Supernatural, a Correspondence between Arnold Lunn and Prof. J. B. S. Haldane (*Review*), 888; in Modern Life, Sir Frederick Gowland Hopkins, 893; Ultimate Values of, Dr. J. C. Merriam, 944; in the Public Press, 948; Museum, Watt Bicentenary Exhibition at the, 1020
Sciences, Boundaries of the, Dr. B. H. Knight (*Review*), 970
Scientific: and Technical Books, Recent, July 27, iii; August 31, iii; September 28, v; October 26, v; November 30, iii; December 28, iii; Books, Quarterly List of, 829; Literature, Publication of, Watson Davis, 579; Management: and Social Problems, 45; A. P. M. Fleming and others, 114; Research in China: the Academia Sinica, V. K. Ting, 208; Publication be Controlled? Should, Prof. T. D. A. Cockerell, 222; and Industrial Research, Advisory Council to the Committee of the Privy Council for, Dr. W. H. Mills, Lord Riverdale, Prof A. Robertson and H. B. Shackleton appointed members of the, 716; Surveys, Co-ordination of, E. W. Fenton, 751
Scoresby, William, the R.R.S., 1934-35, G. W. Rayner, 630
Scottish: Varved Clays, Dating of, Baron de Geer, 611; Marine Biological Association, Millport, Report for 1933-34, 638
Sedimentation, Report of U.S.A. Committee on, for 1932-34, 545
Seismology, Bibliography of, Dr. F. J. W. Whipple, 138; E. Tillotson, 295; Recent Advances in, Dr. F. J. W. Whipple, 782
Selenium: Vapour, Molecular Spectrum of, B. Rosen and M. Désirant (2), 655; Oxide, SeO, Emission Spectrum of the, L. Bloch, E. Bloch and Choong Shin-Piaw, 924
Sensory Hairs in the Ear, Movement of, R. E. Bowen, 120
Seralbumins, Crystallisation of, Prof. R. Wernicke, 30
Serbian Gypsy Cult of the Anvil, Dr. A. Petrovič, 799
Sewage Purification, J. D. Watson, 789
Sex: Education in Schools, Dr. E. P. Phillips, 41; Hormone Group, Synthesis in the, Dr. A. Cohen, 869
Sexes, Equivalence of the (*Review*), 124
Sexual: Regulations and Cultural Behaviour, Dr. J. D. Unwin, 149; Fusion in Hymenomycetes, Cytological Significance of the Nature of, Prof. S. R. Bose, 873
Shansi, China, Archæological Investigations in, C. W. Bishop, 508
Sheep in Australia, Cobalt and 'Coast Disease' of, Marston and Lines, 518
Sheffield University: Dr. F. Davies appointed professor of anatomy, R. T. Percival lecturer in metallurgy (founding), and J. S. Bennett assistant lecturer in metallurgy (founding), 79; J. MacD. Croll appointed lecturer in bacteriology, M. Shaw assistant lecturer in mechanical engineering and Dr. E. S. Duthie demonstrator in pathology, 118; Prof. C. J. Patten and Prof. M. H. Phillips appointed emeritus professors; Dr. H. A. Krebs appointed lecturer in pharmacology; H. E. Collins lecturer in mining; Dr. M. Ritchie assistant lecturer in chemistry; J. Harwood research assistant in fuel technology; Dr. J. W. Rogers Ironmongers' Company research fellow, 768; title of honorary lecturer in physics conferred on Dr. W. H. George; H. T. Protheroe appointed assistant lecturer in metallurgy (founding); grant from the Rockefeller Foundation, 1000
Shellac: Research on, 545; its Production, Manufacture, Chemistry, Analysis, Commerce and Uses, E. J. Perry (*Review*), 589
Shipbuilding by Welding, N. M. Hunter and H. W. Townshend, 906
Ships, Construction of, Developments in the, J. D. Christie, 129
Shrubs and Trees: Ornamental, their Selection and Pruning, A. J. Sweet. Edited by W. P. Wright (*Review*), 701
Siberia, Eastern, Ranges of, Prof. V. A. Obruchev, 919
Sign Language as a Form of Speech, Sir Richard Paget, Bt., 981
Silanes, Preparation of, W. C. Johnson and S. Isenberg, 401
Silkworms, Colour Inheritance in, 271
Silver: Nitrite, Thermal Dissociation of, M. Centnerszwer and T. Checinski, 157; Nitride, Crystalline Structure of, M. Bassière, 844
Sisal, Coir and Oak, Molecular Structure in, Dr. E. N. Miles Thomas and J. Hewitt, 69
Sites of Scientific Interest, Preservation of, Prof. P. G. H. Boswell, 388
Skeletal Movement, A New Type of, Dr. W. K. Spencer, 679
Sky: in August, the, 140; in September, 333; in October, 547
'Slow Neutrons', Velocity of, Dr. O. R. Frisch and E. T. Sørensen, 258
Smithfield 'N' Culture, C. van Riet Lowe, 693
Smoke: Abatement Society, National, Annual Conference, at Bristol, 651; in the West Riding of Yorkshire, Damage caused by, Dr. A. G. Ruston, 651
Snake-bite in the U.S.A., Dr. T. S. Githens, 470
Social: Problems, Scientific Management and, 45; Science 409; Institutions, An Interpretation of, Dr. A. C. Haddon (*Review*), 581; Science Investigation, A. Blair, 607; Conditions: Scientific Methods and the Advance of, Life and Leisure in London (*Review*), 695
Society, Mechanism of, 275
Sociology in the United States (*Review*), 584
Sodium: Niobates, Conductivity and Hydrolysis of the, P. Süe, 43; Migration of, on Tungsten, R. C. L. Bosworth, 74; Magnesium and, *K*-series of, Dr. V. Kunzl, 437
Soil Science, International Congress of, 139; 307; 546
Sokoto Province, Fossil Fishes of, Dr. E. T. White, 876
Solar: Radiation, Measurement of, H. L. Wright, 73; Magnetism, Dr. G. E. Hale, 703; Rays (Ultra-Violet), Action of, on the Skin, and the Accumulation of Cholesterol, A. H. Roffo, 731; System, the, and its Origin, Prof. H. N. Russell (*Review*), 932; Origin of the, Dr. H. Jeffreys (*Review*), 932; Activity and Radio Transmission, 947; Radiation and Weather Studies, Dr. C. G. Abbot, 959

Solid and the Liquid States, Continuity of the, Prof. J. Frenkel, 167
Solomon Islands, Conventionalisation of Design in the, Dr. T. A. Joyce, 304
Solutes, Molecular Polarisation of, and Dielectric Constant of Solvents, Dr. R. J. W. Le Fèvre, 181
Solution, Molecular Polarisation in, Dr. R. J. W. Le Fèvre, 190
Solutions in ar Electric Field, Optical Rotatory Power of, Prof. J. Kunz and A. McLean, 795
Solvents, Dielectric Constant of, Molecular Polarisation of Solutes and, Dr. R. J. W. Le Fèvre, 181
Sommerfeld's Theory of Ground Absorption, Negative Attenuation of Electromagnetic Waves and, Dr. S. R. Khastgir, D. N. Chandhuri and B. Sen Gupta, 605
Sooty Mould Fungi, Miss Lilian Fraser, 150; 1032
Sorghum: Observations on, G. N. R. Ayyangar and V. P. Rao; G. N. R. Ayyangar and P. V. Hariharan, 73; β-Glucosidase of, C. Antoniani, 306
Sound Transmission Measurements at the Bureau of Standards, Recent, V. L. Chrisler and W. F. Snyder, 344
South: Sir James, and Christ's Hospital Boys [1835], 654; and East: Africa, Archæology in, Prof. T. F. Dreyer, 872; African Stone Age Typology, T. P. O'Brien, 475; 760; Africa: Native Races of, The Musical Instruments of the, Prof. P. R. Kirby (*Review*), 3; A Plea for the Establishment of a National Research Council and for the Limitation of a National Research Policy in, Prof. M. M. Rindl, 789; Interesting New Fishes from, J. L. B. Smith, 807; African: Stone Age, Cultural Succession in the, 58; Protectorates and British Pledges, 96; Bullfrog, Carotid Gland of the, Dr. G. Eloff, 108; Fishes, J. L. B. Smith, 687; Association, Earl of Clarendon to be President for 1935-36; presentation of the South Africa medal and grant to Dr. E. P. Phillips and the British Association medal and grant to Miss Margaret Orford, 789; Australia: Mining in, 332; Mining Legislation in, 545; -Eastern Union of Scientific Societies, Annual Congress, 155; -West Africa, Flora of a High Mountain in, J. V. L. Rennie, 157; Africa: Prehistoric Research in, 981; Archæological Research in, 998; African Ricciaceæ, Studies in, A. V. Duthie and S. Garside (1), 1039
Soviet Stratosphere Research, 16
Soviets, Archæological Investigation Under the, 714
Spahlinger Tuberculosis Vaccine, 1022
Spaniodon elongatus, a Noteworthy Specimen of, E. S. Hills, 235
Spanish Academy of Medicine, legacy to the, by Prof. Ramon y Cajal, 431
Spark Counters of the Greinacher Type, A Simple Relay for, Dr. H. Teichmann, 871
Special: Areas (England and Wales), First Report of the Commissioner for the, 323; Libraries and Information Bureaux, Association of, Twelfth Annual Conference, 558; Library Work, Training for, J. D. Cowley, 558
Species: -Hybrid, A Fertile, M. B. Crane, 35; Problem, The, Prof. F. Balfour-Browne, 382; Prof. H. L. Hawkins, 574; Problem, the, K. Fægri, 954
Spectra of SeO and SeO_2, Dr. R. K. Asundi, M. Jan-Khan and Prof. R. Samuel, 642
Spectrum: Biological Effects of Different Regions of the, Dr. L. H. Flint and E. D. McAlister, 561; Analysis, F. Twyman, 609; Dr. H. Dingle, 684
Speech Sounds, Overlapping of, Prof. E. W. Scripture, 759
Speed: and Engineering, A. J. Grant, 366; Prof. B. Melvill Jones, 464; 496
Spektroskopie, Prof. K. W. Meissner (*Review*), 457
Spelæological Research in Great Britain, Proposal for, 98
Spheres in a Viscous Liquid, Measuring the Velocity of Fall of, M. M. Ghali, 234
Spiders, Sense-Organs of, B. J. Kaston; H. Blumenthal, 763
Spin in Detonation, the Phenomena of, 974
Spiral Orbits and the Law of Recession, Dr. V. V. Narlikar and K. V. Sastry, 515
Sponges: New, from the Puerto Rican Deep, Dr. M. W. de Laubenfels, 73; Histology of, D. A. Webb, 993
'Spot' Tests and Delicate Analysis, Reagents for, B. D. H., Ltd., 100
Squirrels, American Ground, and Pneumonic Plague, Dr. W. H. Kellogg, 762
Star: Hot Carbon, Spectrum of a, L. Berman, 401; Photometer, a Contrast, R. Tremblot, 448; New, Calculation of the Initial Radius of a, P. Rossier, 845
Stars: New Theory of the Motions of the, J. Schilt, 74; *B*, with Emission Lines, Absolute Magnitude of, H. Mineur, 234; New, Character and Causes of, 501; The Binary, Dr. R. G. Aitken, Second edition (*Review*), 590; *The Realm of the* (*Říše Hvězd*), 752; Late Type Variable, A. D. Thackeray, 764
Statistical Tests, H. J. Buchanan-Wollaston, 182; Prof. Karl Pearson, 296; Prof. R. A. Fisher, 474; Prof. Karl Pearson, 550; H. J. Buchanan-Wollaston, 722; Prof. E. S. Pearson, 833
Statistics, Official, Guide to Current, of the United Kingdom, 1934, 546
Steam Turbines, C. S. Bradshaw, 520
Steamships of Great Britain [1835], 310
Steel: Wires, 'Work-Hardening', Magnetic Testing of, Dr. T. F. Wall, 611; Acceleration of a Structural Reaction in a, by the Effect of a Mechanical Constraint, P. Chevenard and X. Waché, 963
Steels: Chromium, Dr. R. H. Greaves (*Review*), 243; Stainless, The Book of. Edited by E. E. Thum. Second edition (*Review*), 243; Stainless and Chromium (*Review*), 243
Stellar: Parallax, Observations of. Vol. 2, 229; Parallaxes, General Catalogue of, Schlesinger. Second edition, 229; Atmosphere, Structure of a, W. H. Christie and O. C. Wilson, 267
Stereoscopic Photography: A Note on, Dr. J. R. Baker, 193; J. van Zuylen; Dr. J. R. Baker, 551
Sterols, Acetylcholine and, in Tissues, Interaction between, Dr. G. S. Carter and Dr. L. W. Mapson, 143
Stone: Age: Survivals in Ireland, C. B. Whelan, 72; Typology, South and East African, T. P. O'Brien, 760; Implements of the Adelaide Tribe of Aborigines now Extinct, W. Howchin, 555
Strainers, Prevention of Clogging of, in Rearing Aquatic Organisms, Dr. Ll. Lloyd, 646
Strangeways Research Laboratory, Report for 1934, 368
Stratosphere: Air of the: Composition of the, A. Lepape and G. Colange, 81; Presence of Water Vapour and Carbon Dioxide in the, A. Lepape and G. Colange, 197; Helium Content of the, Prof. F. A. Paneth and E. Glückauf, 717; Threefold Coincidences in the, Vertical Intensity of Cosmic Rays by, Prof. E. Regener and G. Pfotzer, 718
Strawberry 'Yellow-edge' Virus, Aphid Transmission of, A. M. Massee, 73
Stream Field Studies, Direct, New Device for, and its Application, P. Neményi, 649
Streptococcæmia, Remarks on, with Accounts of some new Results of Serotherapy in this Infection, Hyacinthe Vincent, 844
Stress: and Elasticity, Dr. W. A. Scoble and others, 520; Lower Yield Point of, 579
Stresses, Alternating, Strength of Metals under Combined, Dr. H. J. Gough and H. V. Pollard, 919
String Games for Beginners, Kathleen Haddon (Mrs. O. H. T. Rishbeth), 510
Structural Theory and Design: an Introduction to, Theory, Prof. H. Sutherland and Prof. H. L. Bowman. Second edition (*Review*), 625
Structures, Stability of, J. S. Wilson, 568
Strychnos Henningsii, Alkaloids of, M. Rinal and M. L. Sapiro, 312
Study of X-Rays, J. D. Bernal (*Review*), 661
Subject Index to Periodicals, 1934 (*Review*), 596
Submarine Navigation Experiments [1835], 348
Substituents, Influence of, on Organic Reactions: a Quantitative Relationship, Dr. G. N. Burkhardt, 684
Succinic Acid, Researches by the Boiling Point Method on the amount of Impurities in, proposed as a Secondary Thermochemical Standard, W. Swietosławski, M. Wojciechowski and E. Sapiro, 845

Südamerikas, Geologie, Prof. H. Gerth (*Review*), 128
Sugar: Beet, Pests and Diseases of the, F. R. Petherbridge and H. H. Stirrup, 189; Cane, Cut, in Egypt, Deterioration of, Dr. Rosenfeld, 725
Sulphite Waste Liquor, Rate and Extent of Anærobic Decomposition of, by Bacteria of Sea Bottom Mud, B. S. Henry and A. M. Partansky (2), 120
Sulphur: Action of, on Silver, R. Dubrisay, 563; Vapour, Absorption Spectra of, L. d'Or, 1038
Sulphuryl Diamide (Sulphamide), Reactions of, Dr. F. C. Wood, 837
Sumatra: its History and People, E. M. Loeb; The Archæology and Art of, A. Heine-Geldern (*Review*), 664
Sun: Kelvin and the Age of the, C. Turnbull, 761; Forthcoming Eclipse of the, in U.S.S.R., 830
Sunspot: A Recent, 18; An Active, 333; A Naked-Eye, 791; Another Large, 907
Sun's Chromosphere, Oxygen in the, T. Royds, 606
Supply and Demand, Equalising, Capt. H. Macmillan, 947
Supra-conducting State, Thermo-electric Effect and the, Prof. E. F. Burton, F. G. A. Tarr and J. O. Wilhelm, 141
Surface Tension of Viscous Substances such as Tars and Bitumens, Measurement of the, A. Léauté, 311
Suspension flowing through a Tube of Circular Section, Settlement from a, W. B. Morton, 924
Sussex: Weald, Iron Age Site on the, S. E. Winbolt, 214; Duke of, and the Royal Society [1835], 806
Swanley Horticultural College, Dr. Margaret S. Smith appointed lecturer in agricultural chemistry and physics, 233
Swimming Baths and Pools, Cleanliness in, 984
Swine, Inbreeding of, R. E. Hodgson, 265
Switzerland: Noxious Insects of, Statistics, J. and L. Deshusses, 1039
Symbols: Units and, Prof. A. V. Hill, 222; and Nomenclature in Physical Science, 840
Syphilis: Experimental, Y. Manouelian, 197; or the French Disease, G. Fracastoro. With a translation, notes and appendix, by H. Wynne-Finch (*Review*), 586
Szeged, First Chemical Institute, Prof. A. Szent-Györgyi appointed director of the, and professor of organic chemistry at, 511

Table-Poultry, Production, 228
Tanganyika Territory: Windbreaks in, C. J. W. Pitt-Schenkel, 510; Mining in the, 1022
Tanning, Modern Theories of, Dr. D. Jordan Lloyd, 443
Tars: and Bitumens, Capillary Ascent of, A. Léauté, 448; Capillary Separation of, A. Léauté, 731
Tautomeric Selenazoles, Absorption Spectra of, Prof. R. F. Hunter, 1030
Tchécoslovaque: La, étude économique, Prof. A. Tibal (*Review*), 702
Technical: College Buildings, Report on, 215; Education, Industry and, Oliver Stanley, 902
Technics and Civilization, L. Mumford (*Review*), 282
Tectites of Indo-China without Figured Forms, A. Lacroix, 234
Tektites, Origin of, F. Watson, Jr., 105
Telephone Developments, New, 1021
Telescope: Through My, Astronomy for all, W. T. Hay (*Review*), 322; Mirrors, Cellular Construction of, A. Couder, 769
Television: in Germany, 61; in the Cinema, Capt. A. G. West, 98; in Great Britain, 252; Transmission, High-definition, 579; in Australia, 715
Tell Duweir, Excavations at, 1934–35, 113
Tell el-Armana, 1934–5, 485
Temperament: in Industry, Dr. May Smith, 215; Nature of, S. Biesheuvel, 312
Temperature and Living Matter, Prof. J. Bělehrádek (*Review*), 412
Tepe Gawra, Iraq, Excavations at, C. Bache, 149
Terbium, Atomic Weight of, Dr. F. W. Aston; Dr. J. K. Marsh, 112
Termites, F. P. Jepson, 652
Tetanus and Diphtheria Toxins, Comparative Action of the Bile Acids on the, L. Veleuz, 563
Thallium Single Crystals, Diamagnetism of, Prof. S. R. Rao and K. C. Subramaniam, 336
Thames: Gravels, Fossil Human Occipital Bone from, A. T. Marston, 637; River, Estuarial Embankments of the, Dr. B. Cunningham, 637; Dam the, 904; Gravels, Fossil Human Occipital Bone from, K. P. Oakley and Dr. L. S. B. Leakey, 916
Therapeutic Substances, Additional regulations relating to, 601
Thermionic Valves, Miniature, B. Salzberg and D. G. Burnside, 877
Thermo: -Electric Effect and the Supra-conducting State, Prof. E. F. Burton, F. G. A. Tarr and J. O. Wilhelm, 141; -Couple Standardisation, W. F. Roeser and H. T. Wensel, 177; -Compressors, Energy Yield of, J. Rey, 311
Thermodynamic Equilibrium in the Hypothesis of the θ Variable or β Variable, Conservation of the Polytropic character of, G. Tiercy, 845
Thermodynamical Relations for a Simple System, Derivation of, Prof. A. Norman Shaw, 441
Thermodynamics of a Gas, Application of Statistical Mechanics to the, Georgette Schouls, 81
Thiohydrazides, Constitution of the, M. H. Wuyts and Mlle. A. Lacourt, 235
Thixotropic Colloids, Prof. H. Freundlich, 922
Thorium B, Adsorption of, Positive and Negative Carbon Surfaces by, H. R. Kruyt and T. Kruyt, 235
Thorpe's Dictionary of Applied Chemistry. Supplement, Prof. J. F. Thorpe and Dr. M. A. Whiteley. Vol. 2 (*Review*), 7
Three-Carbon Tautomerism, Mechanism of, Dr. D. J. G. Ives and Dr. H. N. Rydon, 476
Thunderstorms and Atmospherics in South Africa, Relation between, D. B. Hodges and Dr. B. F. J. Schonland, 1039
Thyroid Glands, Entire, Culture of, A. Carrel and C. A. Lindberg, 311
Tiedemann, Prof., in Edinburgh [1835], 616
Timber in the Box-making and Coal-mining Industries, 653
Timbers, Indian, Air Seasoning of, Dr. S. N. Kapur, 725
Tin Monoxide, Formation of Mixed Crystals with, E. Hayek, 273
Titanium: Trichloride, Anhydrous, Preparation of, M. Billy and P. Brasseur, 43; Protactinium with, Co-precipitation of, Mlle. H. Zavazziano, 80; Tetrachloride and Hydrochloric Acid, Two New Compounds of, A. Chrétien and G. Varga, 731
Titanothere Remains from the Sespe of California, C. Stock, 488
Tobacco Leaf, Disease of 'Wildfire' in the, Variations of the Physiological Ratios in correlation with the, H. Legatu and L. Maume, 525
Tomato: Virus Diseases, English and Canadian, Drs. G. C. Ainsworth, G. H. Berkeley and J. Caldwell, 400; New Virus Diseases of, Dr. Kenneth Smith, 839
Tongue, The, as a Primitive Sense Organ, Prof. D. Katz, 111
Toronto University, Prof. T. Griffith Taylor appointed professor of geography in, 447
Torsional Vibration: Elementary Theory and Design Calculations, W. A. Tuplin (*Review*), 203; Problems, Practical Solution of, W. K. Wilson (*Review*), 203
Tortugas Laboratory, Research in the, 580
Toxikologische Mikroanalyse, Prof. L. Rosenthaler (*Review*), 973
Transport, Scientific Research in, Lord Rutherford, 997
Travancore, Zoological Gardens of, 470
Tree-Swallows, Survival in, W. Weydemeyer, 399
Trees, The Contribution of, to National Health and Efficiency, R. St. Barbe Baker (Chadwick lecture), 713
Tressé Iron-Age Megalithic Monument, The, Miss V. C. C. Collum, 265
Tripterodon, Playfair, The genus, J. L. B. Smith, 312
Triturus, Gill Formation in the Embryo of, M. Ichikawa, 481

Tropical: Plant Diseases, Dr. E. J. Butler (*Review*), 5; Forest Types, Succession of, Dr. Burtt Davy, 403
Truth, The Search for, Prof. E. T. Bell (*Review*), 493
(*Trypanosoma equiperdum*), Effect of Low Temperature upon Trypanosomes, in Mammals, Dr. N. Kalabuchov and L. Levinson, 553
Tsetse Fly Control, Report on, 601
Tungsten, Migration of Sodium on, R. C. L. Bosworth, 74
Tüpfelreaktionen, Qualitative Analyse mit hilfe von, Dr. F. Feigl. Zweite Auflage (*Review*), 89
Turbine Practice, High-Pressure, 579
Twins, Identical, Dr. J. A. F. Roberts, 72

U_3O_8, Electrolytic Method of preparing Thin Deposits of, M. Francis, 616
Uca pugilator, Colour Changes in, S. P. Carlson, 769
Unemployment, Science and, J. M. Kennedy, 748
Unit of Force in the M.K.S. System, Dr. L. Hartshorn and P. Vigoureux, 397
Units and Symbols, Prof. A. V. Hill, 222
Universe: Age of the, Sir James H. Jeans, 432; Dr. J. A. Chalmers and Bruce Chalmers, 916; Man and the, Sir James H. Jeans (Sir Halley Stewart Trust lecture), 689
Universities and Business Training, Dr. J. A. Bowie, 691
University: Degrees in Engineering, Dr. T. W. Chalmers, 63; Student Housing Conditions, Dr. W. H. Cowley, 271; Education, Cost of [1835], 486; Parliamentary Representatives, 843; 881; of London Council for Psychical Investigation," "The, Prof. A. V. Hill, 955
Upper: Mississippi River, Canalisation of the, 137; Carboniferous Fossils in America and Europe, Prof. T. D. A. Cockerell, 398; -Atmospheric Ionisation, Magnetic Storms and, Prof. E. V. Appleton and Miss L. J. Ingram, 548; Atmosphere: Hydrogen in the, Prof. J. Kaplan, 549; Ionisation of the, Prof. E. V. Appleton and R. Naismith, 557
Upstream Sheet Pile, Influence of an, on the Uplift Pressure on a Floor, Dr. N. K. Bose and H. L. Uppal, 959
Uranine Solutions, Fluorescence of, Comparative action of ordinary Alkaloids and Genalkaloids on the, C. Achard, A. Boutaric and J. Bouchard, 806
Uranium, Isotopic Constitution of, Prof. A. J. Dempster, 180
Urease, Nature of, P. Grabar and A. Riegert, 43
Uronic Acids, Furfural Yield of, F. W. Norris and C. E. Resch, 520

Pasteurization of Milk

THE heat-treatment, or 'pasteurization', of milk before consumption has in the past been the subject of controversy, but as a result of much research and inquiry during the last few years, this measure has come to be generally accepted as the best solution of the several problems presented by the use of raw untreated milk, particularly that of the transmission of infections. Detailed criticism of the application of the pasteurizing process to the general milk supply was, however, formulated by Sir Arnold Wilson in his recent presidential address to the Central Council of Milk Recording Societies of England and Wales last March, and some of the points he raises merit consideration.

It is suggested that the "principal, if not the only, reason" why pasteurization is practised is that it makes it possible to transport large quantities of milk from great distances, and to market it several days after production, in competition with fresh milk. Whatever may have been done in the past, we believe that to-day such a statement is inaccurate. Some 90–95 per cent of London's milk is pasteurized, and the large bulk of this is conveyed in the raw state and treated after arrival, and we question whether anywhere now 'large quantities' of milk are pasteurized for purpose of transport.

Compulsory pasteurization, which has been advocated in some quarters, is viewed with grave concern as being likely to upset present economic conditions, with the deprivation of a number of farmers of their means of livelihood. The Report of the Committee on Cattle Diseases is quoted in support, and the important qualifying paragraphs (Nos. 155–160) are criticised; the reactions that might be caused by such a measure are not considered to be solved by the suggestions made. Dr. Norman Wright, director of the Hannah Dairy Research Institute, surveyed this subject in 1931, however, and concluded that the effect of compulsory pasteurization, were it introduced (and this would probably be only in the larger urban areas), would be to eliminate the casual producer-retailer from large cities, to the advantage of the general body of milk producers, the established producer-retailer eventually becoming the chief purveyor of high-grade raw milk from tuberculin-tested herds. Moreover, this seems to be the experience in New York State, where compulsory pasteurization is general, though the growth of tuberculosis-free herds in Great Britain, where State assistance is lacking, to reach the American standard of freedom from tuberculous infection, would be lamentably slow under present conditions. In this respect, more State assistance is an urgent need in Great Britain.

It has been proved beyond doubt that the infections transmissible by milk—tuberculosis, typhoid fever, scarlatina, diphtheria, undulant fever and others—are destroyed by efficient pasteurization. The risk of tuberculous infection (occasionally other infections also) has, unfortunately, been increased of late by the introduction of the hygienic system of conveyance of milk in bulk, 3,000 gallons or so, in glass-lined road- and rail-tanks, for, should any portion of the milk in such a tank be infected, the whole will become infected. In the case of tuberculosis, in particular, this risk is a real one, for the bulk-milk is necessarily the mixed milk of a number of cows, some of which under present conditions will almost inevitably be infected with tuberculosis. Whereas, before the present system of bulk transport, only at most some 8–10 per cent of samples of milk tested contained the tubercle bacillus, Minett and Pullinger and Pullinger, respectively, found that of 43 and 63 samples of rail-tank bulk supplies examined, every one contained living tubercle bacilli. Undulant fever (*Brucella*) infection was also frequent. It is noteworthy that all these samples, examined after efficient commercial pasteurization, were entirely free from living tubercle bacilli and *Brucella*, certainly a tribute to the value of the process. Sir Arthur Newsholme says in his recent book "Fifty Years in Public Health": "It is for this reason [pasteurization] that milk outbreaks of acute infectious diseases are much rarer now than in the past".

Some 1,500 deaths annually in Great Britain may reasonably be ascribed to bovine tuberculous infection, and it is admitted that human beings may contract tuberculosis from milk and milk products. Sir Arnold Wilson appears to argue that because the mortality from tuberculosis transmitted by milk is so insignificant compared with the mortalities from other forms of tuberculosis and from other diseases, it may be ignored—"We cannot avoid all dangers: we should aim at excluding the greatest, and the bovine [tubercle] bacillus is shown to be among the least". But this view does not take into account the increased risk of infection with the bovine tubercle bacillus introduced by the present system of bulk transport.

The possible damage that may be done to the nutrient qualities of milk by pasteurization requires consideration. It is alleged that the vitamin, calcium and phosphorus contents are diminished, and the general nutrient qualities are lessened. It may be admitted that, in the case of infants subsisting on complete diets of cow's milk, pasteurized milk does seem to be deficient and to require supplementing as regards vitamins and salts, but there is no body of evidence conclusive of the relative merits of raw and pasteurized milk, and the subject demands further investigation. For children the bulk of whose nutritive requirements is satisfied from sources other than milk, Stirling and Blackwood state that there are no good grounds for the belief that pasteurized milk is a less valuable component of the diet than raw milk (*Bull.* 5, Hannah Dairy Research Institute), and Prof. J. C. Drummond, in a series of animal experiments, failed to detect any evidence that pasteurization adversely affects the nutritive value of milk.

Milk pasteurization, if carried out, ought to be efficient and free from any possible source of failure. The recognised system consists in heating the milk to a temperature of not less than 145° F., and not more than 150° F., and maintaining at this temperature for 30 minutes, after which it is cooled. It is obvious that to hold a large volume of milk, it may be up to 500–1,000 gallons in the large plants, within two or three degrees of a particular temperature for half an hour, entails the use of an apparatus the thermal control of which must be one of delicacy and exactitude. If any portion of the whole bulk of the milk is maintained at less than the proper temperature for the requisite time, disease germs may escape destruction; if the temperature rises above the limit, the 'cream line' may be damaged, and an excessive proportion of the lactic organisms, which bring about souring and curdling, be destroyed, so that the milk does not sour normally on keeping, but undergoes undesirable changes that are not apparent to the consumer. It should be emphasised, however, that the modern commercial pasteurizer has reached a high state of perfection, and provided that the plant is properly laid out in the first instance, it can easily do what is required without risk of failure. The statement has been made that pasteurized milk is more liable in the home to become infected than raw milk, presumably because of the destruction of the inhibiting lactic organisms, but the widespread system now in use of retailing pasteurized milk in bottles or other containers must minimise any such problematical risk.

There can be no doubt that at the present time pasteurization is often carried out inefficiently. The Cattle Diseases Committee was so impressed

by the evidence given before it of the importance of securing efficiency for this process that it recommends in its report that pasteurization of milk should be permitted only in plants the design of which has been officially approved, that have been tested on erection to ensure that they conform to the approved design, and are frequently inspected and tested during working by an officer of the sanitary authority. This officer would need to possess knowledge of the practical working of pasteurization plants and of their construction, if he is to carry out his duties of inspection, testing and supervision properly. The information required by officers of local authorities for this purpose has in the past been largely lacking, but is now provided in a report by Sir Weldon Dalrymple-Champneys, just issued by the Ministry of Health ("The Supervision of Milk Pasteurising Plants." *Reps. Pub. Health and Med. Subjects*, No. 77. London: H.M. Stationery Office, 1935. 1*s.* 3*d.* net). In this, the construction of premises and general 'lay-out' of a plant are first described, and then the constituent parts and mode of working are detailed. Considerable space is devoted to the important subject of thermal control, temperature recorders and thermographs, with diagrams and description of these. The subject of bottle cleansing is also considered, and finally—most important for the supervising officer—a tabulated description is given of the principles of, and points to be noted in, the inspection of a pasteurizing plant.

The fear expressed in the past by many medical officers of health and others that pasteurization, by increasing the keeping qualities of milk, would lead to less cleanly production, has not been borne out in practice, and it is probably correct to say that the present standard of hygienic milk production is higher than it ever was.

Viewing the subject as a whole and in its wider aspects, under present conditions the efficient pasteurization of milk appears to have much to commend it, and the advantages to the community outweigh the reputed disadvantages.

Sir Arthur Newsholme is of the opinion that so far from discarding or limiting the pasteurization of our milk supplies, the process should be extended, for he says: "The time is ripe for compulsory supervised and standardised pasteurisation of all milk supplies. This would reduce to a minimum the distribution of disease germs by milk, including especially the distribution of milk containing tubercle bacilli of bovine origin".

African Music

The Musical Instruments of the Native Races of South Africa

By Prof. Percival R. Kirby. Pp. xix+285+73 plates. (London: Oxford University Press, 1934.) 35*s.* net.

THE present volume will be welcomed by all concerned with native music, but particularly by anthropologists, for the twofold interest its subject presents. Musical instruments, on one side, have always been a favourite object for ethnological studies, because as products of handicraft they are part of a people's material culture, and by magic and religious functions they play at the same time a prominent rôle in tribal life. The most ancient culture forms, on the other side, are found surviving among those primitive races who have been compelled to retire into the remotest and least accessible regions, for example, the Fuegians, the Tasmanians, the Andaman Islanders, the Vedda in Ceylon, or the Bushmen in the Kalahari. It is true that in South Africa this isolation even of the most primitive tribes, namely, Bushmen, Hottentots and Bergdama, has since long been far from complete, extensive tribal migrations, or smaller movements, particularly of Bantu negroes, having from time immemorial chequered the map of racial and cultural distribution. This very distribution, however, is the safest, if not the only, basis for a reconstruction of the early history of the country, that is, the history before the arrival of the European explorers.

Prof. Kirby, known as a distinguished specialist from his earlier contributions to scientific periodicals, has attempted to collect, and to present in this book, as comprehensive a material as possibly can be collected in our days. Living in Johannesburg, he had the opportunity during nine great and many smaller excursions into native territory, not only to watch the native musicians, to obtain first-hand information and to collect several hundreds of their instruments, but also to learn to play them himself, which, of

course, is the best way to a complete understanding. Besides, he was assisted in his inquiries by quite an army of able helpers; and for supplementary information he has consulted the literary sources from Fr. João dos Santos (1586) onwards, and compared the instruments which he collected with the specimens in South African and European museums.

Thus, the author has succeeded in compiling an almost complete inventory of musical instruments found south of the Cunene-Limpopo line, comprising under the term 'musical instruments'—as the ethnologist is bound to do—any device for sound-production. The instruments are minutely described, and profusely illustrated by excellent photographs. The technique of playing is explained with the help of musical examples (partly transcribed from phonographic records). A description of the social function of every type, of its ritual, magic or other meanings, and of the occasions of its use, is included, and the distribution among the tribes of South Africa as well as the history so far back as it is possible to go on the evidence of early writers and native tradition, is traced for every instrument.

The only thing likely to be regretted by ethnologists is the lack of physical measurements of the tuning of such instruments as xylophones or reed pipe series; for coincidences in absolute pitch (expressed in vibration numbers) have proved the safest guide in tracing back the instruments to their very origin. Thus the African xylophones, at least the types with calabash resonators, are related to their prototypes in south-eastern Asia and Indonesia not only by their similar shape, playing technique and the characteristic musical scales to which they are tuned, but even by very identity of pitch[1].

Out of the almost inexhaustible wealth of detailed information we owe to Prof. Kirby's work, only a few examples may be selected, which most strikingly show its value for comparative ethnology. The Venda in northern Transvaal have a large bowl-shaped wooden kettle-drum with pegged-on diaphragm (which in itself is an Asiatic way of fastening); when they use it, for example, in their initiation ceremonies, the drum is suspended on the horizontal pole of a frame by means of ropes tied to two of the four drum handles, which are fitted in an ornamental band carved round the drum. Now, the suspension, the style of this carved wave ornament and the four-legged 'handles', which are called 'frog's knee' by the Venda—all these details closely resemble the so-called 'bronze drums' of China and Tonkin, on the plate of which invariably four plastic frogs are placed on the outermost circle of relief ornaments, marking the cardinal points. (In fact, the eastern Asiatic 'bronze drums' are more or less hour-glass shaped and have, apart from the frogs, also 'ears' fixed on the side. For both these traits there are parallels in the drums of the Barotse and other tribes in the southern Congo basin.)

Drums of this kind are also played in pairs, by a man and a woman respectively, in connexion with the reed pipe dances which form an integral part of that most important sacrificial rite which the Venda perform for their royal ancestors in the sacred groves where they are buried. This rite is at the same time a fertility cult to secure the new crops. A similar ritual at harvest time is performed for the spirits of departed women-chiefs, who haunt a certain bamboo bush at a sacred place, guarded by special taboos. From this particular type of bamboo, that is, from the 'female' rods which are hollow (whereas the 'male' rods are solid) the pipe-sets are cut, and tuned by an old man to whom this function is entrusted, the pipe ensembles and dances being a royal prerogative. The leader of the orchestra keeps the instruments, together with the drums and other sacred implements, in the council hut, and is responsible for them to the chief.

We may feel doubtful as to whether a series of stopped pipes distributed among different players—which apart from South Africa is found in Central and East Africa, Lithuania and Upper Burma—should be regarded as a precursory form or as a variant of panpipes. But there is no doubt that in their social function, as exemplified by the Venda customs, there is a striking resemblance to a tradition from the classical land of ancestor worshippers, China. It refers to the very beginnings of Chinese civilisation. Hoang Ti, one of the five mythical emperors, ordered, as tradition has it, his minister Ling Lun (that is, 'master of music') to institute the right foundations of music. Ling Lun went to a certain place far in the west, where the appropriate kind of bamboo grew, and cut the male and the female series of pipes, tuning them to the pitches of the tones which he heard sung by a couple of phœnix birds. The standard-pitch pipes, which by their length represent the basis for the Chinese system of measurement as well, were kept until recently in the Ministry of Measures and Music under the superintendence of one of the Imperial princes. The ancient Chinese pitches still survive on modern panpipes, for example, in Oceania and South America, and on xylophones, for which they must have been adopted originally from the panpipes. For the Venda the real standards seem to be not the pipe-sets, but rather, as Prof. Kirby suspects, a very old set of xylophone slabs. It was, in fact, a Venda xylophone by which the reviewer was first led to

the discovery of the identity of African and Asiatic pitches.

Certain queer types of South African instruments are the product of contact with the various forms of foreign influence. The old Hindu bar-zither, which was played rested on the left shoulder, with its resonator up and the peg down, is popular with many South African tribes. Here it is still held in the old way, but the original gourd-resonator has more recently been exchanged for a paraffin tin, and instead of plucking the string one uses a miniature friction-bow. The instrument is thus made to resemble an Arabic fiddle from the Sudan, held upside down. Or we find a vertical flute, with two or three finger-holes near the lower, stopped end, and a globular fruit shell for a mouth-piece on the upper end, which is played by Karanga and Venda boys. It looks as if a clarinet of the 'pibcorn' type (spread from Java over Southern Asia and Southern Europe finally to England) had lost its reed, thus rendering useless the mouth-piece which had served as a wind-chamber. A mixture between a North African clarinet and a globular flute occurs in North-West Africa. The most curious fact, however, is that the Karanga performer, when playing this flute, sings at the same time a short tune. Even this practice has its counterpart in some other part of the world, namely, among the Maori of New Zealand, who used to 'speak' on their flutes[2], and possibly among the Australians, who do not blow their trumpets, but use them merely as megaphones.

Tropical Plant Diseases

(1) The Diseases and Curing of Cacao

By Prof. H. R. Briton-Jones. Pp. x+161. (London: Macmillan and Co., Ltd., 1934.) 10*s*. net.

(2) Diseases of the Banana and of the Manila Hemp Plant

By Dr. C. W. Wardlaw. Pp. xii+615. (London: Macmillan and Co., Ltd., 1935.) 30*s*. net.

THERE are several reasons for welcoming the first two of the manuals on the diseases of the major crops of the British Colonies, the need for a series of which was so strongly voiced at the Imperial Mycological Conference in 1929. They are from the West Indies, among the oldest of the Colonies and the most tried by the ravages of plant diseases. They have been written by members of the professorial and research staff of the Imperial College of Tropical Agriculture in Trinidad, where most scientific officers of colonial agricultural departments now complete their training, and are a testimony to the activity of that centre. They reflect the modern approach to phytopathology as concerned with safeguarding the health of the crop in its widest aspects, of which parasitic attack is but one. They are attractively written and produced, well illustrated, and with full and up-to-date bibliographies. In each case the important crop covered (Trinidad has 200,000 acres under cacao, and bananas are the mainstay of the export trade of Jamaica) is suffering from an epidemic disease which is causing much alarm.

(1) Prof. Briton-Jones's book on cacao diseases is written to interest, and be readily understood by, the educated planter. The diseases are clearly described, their cause indicated with as few technicalities as may be, and their control fully discussed. A chapter is given to the formidable witches' broom disease caused by *Marasmius perniciosus*, which reached Trinidad in 1928, though long known on the mainland of South America and doubtless indigenous in some part of that natural home of the cacaos. The disease in Trinidad is following the slow course which gradually extinguished cacao-growing in Surinam, and is not of the virulent type which caused a crisis in Ecuador in a few years after it first appeared there in 1921, probably coming from the Amazon basin, where it has recently been discovered to be widespread. It is in this area that the search for varieties that may be immune from infection is most likely to be fruitful. Breeding for resistance, however tedious, may be the only satisfactory means of control, though Prof. Briton-Jones indicates measures directed to increase the crop yield sufficiently to render the costly control by hand-picking the diseased parts profitable.

A useful section of this book, with a separate bibliography, is given to the preparation and curing of cacao.

(2) Dr. Wardlaw's book on the diseases of the banana, *Musa sapientum*, and the botanically allied Manila hemp plant, *M. textilis*, is planned on a more generous scale than the other. More is known of banana than of cacao diseases, and there are more of them; the useful list of fungi and bacteria recorded on the banana which Dr. Wardlaw has compiled

includes more than fifty parasites, not counting several virus diseases destructive in Australasia and the Far East and beginning to appear in the New World. The discussion of each disease is exceptionally full, well documented, and often enriched by the author's personal studies; scientific details are not spared, and the book will appeal as much to the professional plant pathologist as to the planter. A valuable section deals with the wastage of the fruit in transport and storage, based largely on the author's work at the Trinidad Low Temperature Station.

In this book also one disease, the wilt or 'Panama disease' caused by strains of *Fusarium oxysporum*, receives extended treatment on account of its outstanding economic importance. Unlike cacao witches' broom, it occurs in most parts of the world where its host plant is grown, but it is only in the West Indies and Central America that it has proved a scourge; there is little doubt that this is due to the almost exclusive cultivation for export in this area of the highly susceptible but unrivalled shipping variety, the Gros Michel. The wilt is decimating the Gros Michel plantations of Jamaica, and has caused the abandonment of many thousands of acres of rich banana lands in Central America. But, unlike cacao witches' broom, practical immunity from wilt is possessed by several more or less well-known edible and wild bananas, and breeding for disease resistance combined with shipping qualities is already well advanced both in Jamaica and at the Imperial College in Trinidad. One may question some of the author's views regarding the parasitism of the wilt-inducing fungus, without in any way belittling his achievement in the preparation of this manual.

Both of these works should have a place in the libraries of colonial agricultural departments and of their plant pathologists. E. J. BUTLER.

Galileo and the Leaning Tower of Pisa

Aristotle, Galileo and the Tower of Pisa

By Prof. Lane Cooper. Pp. 102. (Ithaca, N.Y.: Cornell University Press; London: Oxford University Press, 1935.) 7*s*. net.

IT is generally believed that Galileo, as a young lecturer on mathematics and physics at the University of Pisa, gradually became convinced of the untrustworthiness of many of the statements which were currently believed and taught on the authority of Aristotle. Indeed, he has been stated to have incurred a certain amount of unpopularity on account of the subversive nature of his views. Among other things he doubted the truth of the oft-repeated statement that when two dissimilar weights are dropped, the heavier will reach the ground sooner than the lighter in proportion to their weights; accordingly, so we have been assured, Galileo determined to try the case, and after ascending the Leaning Tower of Pisa with a 10 lb. shot and a 1 lb. shot, he let them fall. "Together they fell, and together they struck the ground," to the confusion of all the onlookers who held the so-called Aristotelian view.

This story has been retold with variations by many historians of science, and the historic occasion has been marked as a turning point between the ages of the older traditional, and of the newer or experimental philosophies.

Prof. Lane Cooper, of Cornell, being desirous of studying the evidence for this Leaning Tower experiment, and finding that there is no book to which a student with limited access to foreign or ancient books can refer, has now made a critical study of the literature and has reprinted many relevant quotations, with English translations where necessary. In the whole collection he has satisfied himself that no one passage can be accepted as proof that Galileo, in 1590–91, or before he left Pisa for Padua in 1592, did ascend the Tower and do his historic experiments either alone, or in the presence of "the whole body of students" of the University.

There is no need to cite here any of the modern versions of the story, but it is curious that Prof. Cooper should not have mentioned the excellent life of Galileo by J. Elliot Drinkwater in 1829. The relevant points are these. Galileo died in 1642, never having once alluded in any of his own writings to the Leaning Tower or to experimenting from it. His biographer, Viviani, writing in 1654, states that he proved that moving bodies of the same material but of unequal weight all moved at the same speed by repeated trials (*con replicate esperienze*) from the height of the Campanile of Pisa, "in the presence of the other teachers and the whole assembly of students". As a result "his rivals, stirred with envy, were aroused against him".

Prof. Cooper points out that if this be a true presentation of the case, it is extraordinary that

there should be no reference in contemporary literature to so important an occasion.

A "Comparison of Aristotle and Plato" was published by Mazzoni in 1597 in which Galileo's principles of motion are accepted, but although the writer is in opposition to Aristotle, he does not allude to any researches of Galileo at Pisa. Again, when Coresio in his "Operetta intorno al Galleggiare de Corpi Solidi" (1612) entered into controversy against Mazzoni, he would certainly have referred to such experiments had they been made publicly at Pisa. Further, Renieri, Galileo's own successor in the chair of mathematics at Pisa, did indeed make experiments from the Tower in 1641 and wrote to Galileo about them, but there is no suggestion in their correspondence that similar experiments had ever been made there fifty years earlier, nor did Galileo allude to his having done anything of the same nature.

What is known of Galileo's work is derived from: (1) his manuscript "De Motu", written about 1590, consulted by Viviani in 1654, but not published before 1883; (2) his "Discorsi Matematiche intorno à due Nuove Scienze", published in 1638, in which two imaginary characters, Simplicio and Salviati, discuss in dialogue the laws of motion, evidently as contained in the "De Motu". In all this there is nothing about Pisa or about experiments during Galileo's sojourn there.

On the other hand, a number of men of science much earlier in the sixteenth century had already attacked the view then attributed to Aristotle, that bodies fall with a speed proportional to their weight. Among these were Giovanni Battista Benedetti, in his "Demonstratio proportionum motuum localium contra Aristotelem et omnes Philosophos", Venice, 1554, who was followed by Jean Taisnier "Opusculum", 1562; Cardan "de Proportionibus", 1570; Beato of Pisa, Ghini of Bologna and others, and especially by Stevinus of Bruges. Their previously printed works would have deprived any Leaning Tower experiment of 1590 of the originality that was claimed by Viviani sixty years after the supposed great day of Galileo.

In conclusion, Prof. Cooper rightly accuses Galileo of causing his 'Salviati' to affect to quote from Aristotle words that are not found in Aristotle's writings; and it is possible that in this has lain the cause of all the trouble.

So far the author's case appears strong. It is when he comes to deal with Aristotle's supposed views that his arguments incline to the irrelevant. He admits that Aristotle must, if pressed, have said that bodies would fall at different rates, so that his disquisition on the meaning of πίπτειν and 'falling' is immaterial.

Aristotle would have naturally used the word ῥοπή because he considered velocity as a quality inherent in the body itself, instead of something relative. What is really interesting is the long tradition of opposition to Aristotle that goes back far beyond Galileo, indeed even to the days of Philopon, as shown by his commentary on Aristotle's "Physica", written about A.D. 533.

Although we consider that Prof. Lane Cooper might have marshalled his material rather better, we are grateful to him for directing our attention to so important a field of historical study.

R. T. GUNTHER.

Thorpe's Dictionary of Applied Chemistry. Supplement

By Prof. Jocelyn Field Thorpe and Dr. M. A. Whiteley. Vol. 2: *N*—*Z*. Pp. xx+727. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1935.) 60*s*. net.

THE second supplementary volume of Thorpe's "Dictionary of Applied Chemistry" departs from the original plan only in that it was not found possible to include an index, which will be published with a glossary in a third volume. Some of the articles are supplementary to those which appeared in the main series of volumes, for example, those on naphthalene by Prof. W. P. Wynne and Miss Turner, on proteins and their degradation products by Dr. W. V. Thorpe, on radioactivity and radium by Dr. A. S. Russell, on spectroscopy by Dr. R. A. Morton, on terpenes by Prof. J. L. Simonsen and on vitamins by Dr. L. J. Harris. On the industrial side, there is a very fully-documented article by Prof. J. R. Partington on the utilisation of atmospheric nitrogen, a long and well-illustrated article on petroleum by Dr. A. E. Dunstan, in addition to supplementary articles on sodium and potassium by Dr. R. N. Kerr, and on paint and varnish by Dr. R. S. Morrell.

New articles are those on the parachor by Prof. S. Sugden, on free radicals and on rhenium by Dr. T. G. Pearson, on the stereo-chemistry of cyclic compounds by Dr. W. H. Mills, on tautomerism by Dr. J. W. Baker, and on heavy water by Prof. H. V. A. Briscoe. On the industrial side, Dr. C. H. Lander contributes a new article on oil and petrol from coal. A curious limitation in the scope of the work is indicated by the fact that, whilst supplementary articles are provided on photography, photosynthesis and polarimetry (mainly in reference to new types of molecules exhibiting optical rotatory power), the general subject of photochemistry is not even indexed either in the original or in the supplementary volumes.

Since only the glossary and index are now outstanding, it may be said that the revision of the "Dictionary" has brought together a large amount of information that is not readily available in other publications, and that its value and usefulness are fully maintained by the new supplementary volumes.

Proceedings of the Fourth International Congress for Applied Mechanics, Cambridge, England, July 3rd-9th, 1934

Pp. xviii+283. (Cambridge: Printed at the University Press, 1935.)

THIS beautifully produced and illustrated book contains full reports of six general lectures together with short abstracts of more than a hundred sectional papers arranged alphabetically. The abstracts deal mainly with problems in mechanics, elasticity and hydraulics and their applications to elastic fatigue and plastic flow of solids and viscous and turbulent flow of liquids.

The first lecture, by V. Bush, on recent progress in analysing machines, describes an optical instrument for the evaluation of parametric integrals and solvers for simultaneous linear algebraic equations and for ordinary differential equations. The second by A. Caquot, on the definition of the elastic domain in isotropic media and intrinsic curves of apparent and true elastic resistance, after a brief review of the relevant classical concepts, treats of the relation between the magnitude and direction of the stress required to produce a permanent strain in concrete and steel, found experimentally and applied to the determination of the elastic limit. J. P. Hartog in the third lecture considers the vibration problem in engineering, with reference to instabilities caused by friction, phenomena in stretched wires and vibration caused by leakage flow.

The fourth lecture, by Th. v. Kármán, treats of some aspects of the turbulence problem, especially the stability of laminar motion, the transfer of momentum, vorticity and heat in turbulent motion, with practical applications, and atmospheric turbulence. In the fifth lecture E. Schmidt discusses the convection of heat for independent flow as well as for flow due to differences of temperature, in both its experimental and theoretical aspects, and the extension of the theory to problems of diffusion. The sixth lecture, by H. Wagner, deals with the steady gliding of bodies along a water surface and the landing and taking off of hydroplanes.

Science and Education in the U.S.S.R.

By Prof. A. Pinkevich. (The New Soviet Library, 12.) Pp. 176. (London: Victor Gollancz, Ltd., 1935.) 3*s*. 6*d*. net.

THE success of the planned economy of the Soviet Government probably depends as much upon education as upon any other single factor. This lucid but admirable account of what has already been done to provide the State with intelligent citizens, industry with competent workmen and efficient technicians and leaders, indicates the extent to which a population 64 per cent illiterate in 1917 is being converted into a nation capable of enjoying the advantages with which modern technology can endow it, as well as producing the technicians required for the execution of its plans. Prof. Pinkevich's survey of the position of scientific work in the U.S.S.R. reveals unparalleled co-ordination of such effort in the service of the national economy.

The Annual Register:

A Review of Public Events at Home and Abroad for the Year 1934. Edited by Dr. M. Epstein. Pp. xii+318+182. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1935.) 30*s*. net.

THE troubled history of last year with its many political crises and its social changes and economic problems is fully and impartially recorded in this valuable annual volume. About one third of the book is occupied with the history of Great Britain and the British Empire, the latter arranged under the different Dominions and India. Another third deals with the history of foreign countries, among which even the smallest find a place. The activities of the League of Nations are also reviewed. The final third is devoted to a chronicle of notable events, obituary notes, and lengthy surveys of literature, art, drama, music, finance and law, with fifteen pages of a record of scientific achievement which includes mention of notable books. Several public documents are given in full, including the memorandum on disarmament laid before Parliament on January 31, 1934. A full index enhances the value of the book.

Metallurgy: an Elementary Text-Book

By E. L. Rhead. New, revised and enlarged edition. Pp. xiv+382. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1935.) 10*s*. 6*d*.

A BOOK which is forty years old can claim to have established itself as useful. In spite of the fact that large additions have been made in many sections, the total length remains less than 400 pages, a sign that the matter has been condensed. In this edition new sections have been added on pyrometry, metallography and foundry work, and additions made in the sections dealing with fuel, electric furnaces, coking plant and other melting and smelting processes.

The revival of interest and prosperity in our iron and steel and metallurgical industries should attract an increasing number of technically trained men into them; indeed without these the revival will not persist.

Unit Processes in Organic Synthesis

P. H. Groggins, Editor-in-Chief. (Chemical Engineering Series.) Pp. xii+689. (New York and London: McGraw-Hill Book Co., Inc., 1935.) 30*s*. net.

THE chemist in industry is far more interested in the reaction, mechanism and technique of the processes employed than in the countless new carbon compounds which are synthesised; hence a text-book of organic chemical engineering which deals with the unit processes. Those chosen are nitration, reduction, diazotisation, halogenation, sulphonation, amination, oxidation, hydrogenation, alkylation, esterification, hydrolysis, Friedel and Craft's reaction, polymerisation. There is little doubt that this is the way to teach the subject, and that the new method will in time prevail.

The technical production of the book is excellent.

The Meaning of Biological Classification*

By Dr. W. T. Calman, F.R.S.

IN much of the academic teaching of biology at the present time, the view is expressed or implied that biological classification is meaningless except as a more or less convenient device for filing herbarium sheets or arranging our animal specimens on shelves, the inference being that our search for a natural system of classification is futile, because no natural system exists. It is possible that if we could cross-examine one of those who despise the work of the systematist, we might find him reluctant to go quite so far as this. We all, even the youngest of us, profess to accept the doctrine of evolution, if only as a convenient weapon with which to meet the fundamentalists, and we can scarcely believe in evolution while denying altogether that, in Darwin's words, "community of descent . . . is the bond which, though obscured by various degrees of modification, is partially revealed to us by our classifications". Darwin, indeed, saw clearly, so early as 1842, that "the natural system ought to be a genealogical one" and the idea was old even then. It is implicit in Buffon, in 1766, and Lamarck seems to take it for granted. Why then must we now abandon it, and what is to take its place?

In the 'eighties of last century, a fresh direction was given to morphological thought by the rise of the new branch of biology to which Roux gave the name of *Entwicklungsmechanik*. This was an attempt to explain structure in terms of forces acting during the life-history of the individual organism, and to replace the 'historical morphology' of the period immediately preceding it by 'causal morphology'.

The profound influence which this school has exerted on biological thought is well known. In the passage which I have just quoted from Darwin I omitted one clause: Darwin wrote, "community of descent, the one known cause of close similarity in organic beings". It is not too much to say that causal morphology has revealed other factors besides community of descent as responsible for some of these close similarities. In other words, it has not only proved the possibility, but also explained a method, of convergent evolution on a scale unsuspected in Darwin's time.

This physiological point of view has tended to concentrate attention on those features of organic form that can be demonstrated experimentally to originate as individual responses to the pressure of environment, or to be the inevitable outcome of 'laws of growth' that are the same for organisms in different lines of descent. It has tended to neglect features for which no such explanation can as yet be imagined.

There is, however, one group of biologists who have never quite lost interest in questions of descent. Those who are concerned with the study of fossil animals and plants cannot, if they would, ignore the historical succession of organisms; nor can they altogether avoid speculating on the nature of the links that relate each form to those that precede and those that follow it in the geological time-scale. Here again we find that modern research has led to the recognition of many incontestable instances of parallel and of convergent evolution. I need not illustrate this by citing examples, for the subject was admirably expounded only a few years ago by one of the most erudite and philosophical of palæontologists, the late Dr. F. A. Bather, in a presidential address to the Geological Society. His conclusions were that "the whole of our system, from the great Phyla to the very unit cells, is riddled through and through with polyphyly and convergence", and, in regard to the main subject we are considering here, "Important though phylogeny is as a subject of study, it is not necessarily the most suitable basis of classification".

When these words were uttered, they sounded to some of his hearers like a counsel of despair; and now that their author no longer abides our question, we are left doubting what other possible basis of classification he could have had to suggest to us.

It would be mere presumption on the part of one who is not a palæontologist to criticise on palæontological grounds the deductions of an acknowledged master in that science; but I must confess to a suspicion that things are not quite so bad as Dr. Bather painted them.

The number of instances in which the succession of fossils has been traced upwards through successive strata foot by foot with marvellous continuity must not blind us to the fact that such

* From the presidential address to the Linnean Society of London on May 24.

instances are, in the nature of things, quite exceptional. Darwin's chapter on the "Imperfection of the Geological Record" is, on the whole, as applicable to the state of knowledge to-day as it was when it was written. Many of the phylogenies which have been based upon palæontological evidence are little less conjectural than those based on morphological evidence alone. The main difference (and, of course, a very important one) is that palæontological series can only read in one direction, while we are sometimes in doubt which end of a morphological series comes first.

When these considerations have been allowed for, however, we have to admit that palæontology has revealed instances of convergence that are beyond question, although they are far from proving it to be so all-pervading as Dr. Bather suggested.

It would be easy to multiply instances to show that convergence has been too lightly assumed by some phylogenists as an easy way of getting over difficulties; but, on the other hand, it is impossible to construct a reasonable scheme of phylogeny for any considerable group of organisms without finding it necessary to admit convergence in certain important characters.

When confronted with such examples of convergent, or, as Darwin called it, analogical resemblance, we are tempted to ask where we are to stop. Is structure ever an indication of phylogenetic affinity? Is community of descent ever a cause of organic similarity? Is blood ever, in fact, thicker than water? Dr. Bather, as we have seen, came very near to answering these questions in the negative.

Most morphologists have believed that, however exact the resemblance produced by convergence, investigation would always reveal the underlying evidence of descent. As Darwin put it, "In all such cases some fundamental difference in the growth or development of the parts, and generally in their matured structure, can be detected".

We must, however, beware here of a very ancient type of fallacy.

"Treason doth never prosper. What's the reason?
Why, if it prosper, none dare call it treason."

Convergent evolution, if carried out to the end, would obliterate the evidence of its own existence. Can we believe that it never does so?

I do not profess to have any ready-made and conclusive answer to this question, but it seems to me that it might be helpful to approach it from another side; from the side, namely, of the pure systematist.

Throughout great sections of the animal and vegetable kingdoms the broad outlines of a consistent and symmetrical natural system have now been established beyond all possibility, as it seems, of question. It is true that there still remain very considerable assemblages of both animals and plants of which the classification is still tentative and open to dispute. Since it is upon these debatable groupings that research and discussion have naturally concentrated, we may need sometimes to be reminded how extensive is the territory within which we no longer discuss the natural classification because it has long ago been settled, taken for granted, and put out of mind. Just as, for many of us, fading memories of the Latin grammar consist mainly of lists of exceptions, lingering on after the rules themselves have been forgotten.

It is certain that a natural system does exist. We may never be able to see all the details of its structure, and even its broad outlines may remain, here and there, a little blurred, but the general pattern cannot be mistaken. The framework of the *Systema Naturæ* is something different in kind from the framework of the London Telephone Directory. It is an objective fact, not an arbitrary construction of human inventiveness. It calls for explanation as urgently as, for example, the periodic classification of the elements; and no scientific explanation other than that offered by community of descent has ever been given.

If Dr. Bather and those who think with him were right; if the whole of the system were "riddled through and through with polyphyly and convergence", then it is inconceivable to me that the resulting ruins would have presented anything resembling the coherent pattern that we observe in our approximations to the natural classification of animals and plants. As Darwin pointed out in the fourteenth chapter of the "Origin", the categories of our classification cut across the categories of adaptation and those of environment. To suppose that they can be attributed to inherent laws of growth seems to verge upon mysticism.

I suggest, therefore, that the results of taxonomic research are, in their broad outlines, entirely inconsistent with the view that convergent evolution has been the rule rather than the exception in the phylogeny of animals and plants. It has often played an important part, but never the dominant one.

To know something of the course of evolution is a desirable preliminary to discussing the causes of evolution. If taxonomy can make a contribution towards our knowledge of the course of evolution, then it is a subject worthy of study.

The Institute of Chemistry

By Dr. Bernard Dyer

NEXT week the Institute of Chemistry will celebrate by a banquet and a reception the fiftieth anniversary of the granting of the Royal Charter which, in 1885, rewarded its already many years of effort to establish a definite form of recognition of the profession of chemistry as distinguished from the calling of pharmacy, with which in the lay mind it has been too often confused.

Before the letters F.I.C. or A.I.C. were used to designate fellows or associates of the Institute, there was no specific label by which the analytical and consulting chemist, the teacher of chemistry or the chemical research worker could briefly suggest the nature of his profession, except the vaguely significant letters indicative of fellowship of the Chemical Society—awarded not altogether without discrimination, but carrying with it no diplomatic significance; for the charter of the Chemical Society gave it no power to confer an examinational qualification.

In the late 'sixties and early 'seventies of last century, the desirability of some such distinction was, from time to time, discussed at formal and informal meetings, and in letters and articles in the Press; and in 1875, on the initiative of F. A. Manning, a well-known London analyst, a small organisation committee was formed to endeavour to formulate a definite plan of action. This committee was, from time to time, enlarged and reconstructed, and divers proposals were considered, with the result that two years later, in 1877, the Institute of Chemistry was incorporated under licence of the Board of Trade.

The first president was Prof. (later Sir Edward) Frankland (of the Royal School of Mines), and the other original subscribers to the deed of incorporation were Prof. Abel, Dr. Angus Smith, Prof. J. H. Gladstone, Prof. E. V. Tuson, Prof. W. Noel Hartley, F. A. Manning, E. Neison (later E. N. Nevill), Prof. Galloway, C. T. Kingzett, Prof. J. Attfield, Dr. C. A. Alder Wright, Dr. James Bell, Michael Carteighe, Prof. Crum Brown, and Prof. (later Sir) William Crookes. Of these signatories it is pleasant to be able to record that two are still with us, namely, Mr. E. N. Nevill (known to us then as Neison) and Mr. Charles T. Kingzett. Many chemists who had already given support to the movement in its preliminary stages were registered as original fellows, while admission was offered for the next six months to all whose positions or other evidence of fitness should commend them to the Council. After this, admission was to be restricted to applicants who had gone through a definitely stipulated course of training and experience; and the passing of a practical examination held by the Institute itself was soon prescribed as an additional requirement.

It was during these first six months that the writer of these notes—already in practice as a consultant at an age which would, in these days, surely seem precocious—was elected; but, as he remembers, he had at first to be satisfied with the rank of associate, until he attained the full age of twenty-four years fixed for admission to the title of fellowship. This, otherwise insignificant, incident is mentioned merely to indicate the duration of his association with the Institute and its activities, which is his excuse for yielding to the editorial invitation to occupy this space. The number of fellows and associates of the Institute recorded at the end of its first year was only 275. To-day its roll extends to considerably more than 6,000.

After three years, Prof. Frankland was succeeded as president by Sir Frederick Abel, who in turn was followed in 1883 by Prof. Odling, of Oxford, to whom fell, in 1885, the pleasure of announcing the reception of the Royal Charter, the grant of which forms the subject of the forthcoming Jubilee Celebration. The next president was Dr. James Bell who, in turn, was followed by Prof. (afterwards Sir William) Tilden, during whose time (1891–94), after a nomadic existence in temporary offices and reliance on the hospitality of the Chemical Society for general meetings, the Institute became possessed of a home of its own in Bloomsbury Square. It was also during Tilden's presidency that the Council was fortunate in obtaining the services in its secretarial office of a modest young man named R. B. Pilcher. The post of secretary and registrar had, from the beginning, been filled by Charles E. Groves (the well-known editor of the *Journal of the Chemical Society*) who had recently retired, being succeeded by Mr. G. H. Robertson, whose term of office, however, was cut short by illness. For the time being, Prof. J. Millar Thomson assumed the office of honorary registrar and secretary, with Mr. Pilcher as his lieutenant, and later (in 1900), when Thomson

became president, the full title of registrar and secretary fell to Mr. Pilcher, to whose zeal and energy the Institute owes not a little of its development and usefulness during the last thirty-five years.

Prior to Thomson's elevation to the chair, two other presidents had succeeded Tilden, namely, Dr. W. J. Russell (of St. Bartholomew's Hospital) and Sir Thomas Stevenson, the distinguished toxicologist. The presidency of the latter is chiefly memorable for the institution of the special examination in the analysis of food, drugs and water, and in microscopy, pharmacology and therapeutics, designed to meet the requirements of the Local Government Board (now the Ministry of Health), in considering the qualifications of candidates for appointment as public analysts, and the special diploma of the Institute has ever since been accepted by the Ministry as evidence of competency in this special work.

Succeeding presidents of the Institute were David Howard, Prof. Percy Frankland, Sir George Beilby and Prof. Raphael Meldola. It was during the term of office of the latter that, the lease of the Bloomsbury Square house having expired, the Institute migrated into the present commodious premises which, with the help of a generously supported building fund, it had been able to erect in Russell Square.

Meldola was succeeded in the chair by Sir James Dobbie (the then Government Chemist), whose influence helped to effect a long-contemplated and momentous change in the regulations for admission to the associateship. Hitherto all candidates had to be examined by the Institute itself, but it was then decided that the attainment of high chemical honours at the degree examination of any recognised university should be accepted as sufficient qualification. Promotion to the fellowship, however, was still, as now, to be awarded only after subsequent experience and the passing of a final examination in a special branch of chemistry, pure or applied, unless in exceptional cases in which the carrying out of advanced research, or the rendering of other signal service to chemistry, might be regarded by the Council as justifying exemption.

Later names on the list of past presidents are those of Sir Herbert Jackson, A. Chaston Chapman, Prof. G. G. Henderson, Prof. A. Smithells and Sir Christopher Clayton, while the now acting president is Prof. Jocelyn F. Thorpe (of the Imperial College) who has recently had the satisfaction of announcing that in celebration of its Charter Jubilee the King has been graciously pleased to accord to the Institute His Royal Patronage.

To attempt here any adequate indication of the present multifarious activities of the Institute would be futile; but it should be recorded that it has in Great Britain and in Ireland fourteen local sections, and at least five in the Dominions, all of which hold local meetings for the delivery of lectures and the discussion of papers, while in London advanced 'Memorial' lectures are given from time to time by eminent masters of special branches of science or of technology. The Council is always ready to lend advisory aid in administrative or other matters of public importance in which chemical considerations are involved, and sends representatives or delegates to many external conferences or standing committees. Not the least of the episodes in its history calling for retrospective satisfaction is the very multifarious help, civil as well as military, which, collectively as well as by individual effort, the Institute was able to render to the country during the War.

It should be added that the Institute issues a quarterly journal which records the proceedings of the Council and the activities of the various local sections and other items of domestic interest; and, in addition, often includes editorial articles which are not only informative but also healthily stimulative.

Obituary

Dr. C. E. St. John

CHARLES EDWARD ST. JOHN, who died on April 26 of pneumonia after a short illness, was one of the most lovable of men. Born on March 15, 1857, at Allen, Michigan, he graduated at the Michigan State University and studied afterwards at Harvard and Berlin. He was an instructor in physics at the Michigan State University and in 1897 became assistant professor, and later professor, of physics and astronomy at Oberlin College, and later dean of the College of Arts and Sciences. In the midst of these busy duties he found time in the summer to work at the Yerkes Observatory with Nichols on the measurement of radiation from the stars. At forty-nine years of age he joined Hale at the Mount Wilson Observatory and remained on the staff there until 1929 when he retired. He was made a research associate in 1930 and continued actively working, despite failing health, until the end, his last piece of work (left unfinished) being a general discussion of the problem of solar rotation.

It is as an enthusiastic and most successful

research worker in the general field of solar spectroscopy that St. John will be remembered. Among the problems that he worked at we may mention the gravitational displacement to the red of lines in the solar spectrum in accordance with the general theory of relativity. Closely allied with this was the study of systematic convection currents in the solar atmosphere invoked by St. John to account for anomalies in the observed Einstein effect. A full discussion of the Evershed effect in different levels in the sun's atmosphere in the immediate neighbourhood of sunspots was one of St. John's methods of analysing the layers in which the various Fraunhofer lines originated.

St. John's wide and exact knowledge of the solar spectrum in all its variants made of him a natural leader for the team recently engaged in the revision of Rowland's Preliminary Table of Solar Wave-Lengths, for St. John had been elected in 1922 president of the Commission on Standard Wave-Lengths and Tables of Solar Spectra of the International Astronomical Union. Later, when several of the solar commissions were combined into one—the Commission on Solar Physics—St. John was appointed its president, and he only gave up his active work for the Union a few months ago on account of failing health. He will be greatly missed at the coming meeting of the Union. St. John was also a member of the Commission on Solar and Terrestrial Relationships working under the International Council of Scientific Unions. He was elected an associate of the Royal Astronomical Society in 1917.

Mr. J. T. Cunningham

OF Joseph Thomas Cunningham, whose death occurred suddenly in London on June 5, at seventy-six years of age, it can with truth be said that he, more perhaps than most, through fair weather and through foul, preserved his youthful keenness and eagerness for biological research to the very end of a long life.

Born in London and educated at St. Olave's Grammar School, Southwark, Cunningham went up to Oxford, where his career was brilliant. He was Brackenbury science scholar of Balliol from 1878–81 and obtained first classes in mathematical moderations and in natural science. In zoology he was a pupil of Rolleston, who died in 1881. He was elected to a fellowship at University College, Oxford, in 1882, which he held until 1889.

After working for a time with Ray Lankester, Cunningham spent the winter of 1882–83 at the Naples Zoological Station. His first publication (*Q.J.M.S.*, Jan. 1882) was a review of recent work on karyokinesis. In 1883 he contributed to NATURE a description of the Naples Station, the occasion for which, he says, was the new Department of Comparative Physiology about to be opened there. In July of the same year there appeared two papers on his first researches, dealing with the nephridia of *Patella* and *Aplysia*.

Cunningham's career as a marine biologist commenced when, in 1884, after having been for a short time assistant to the professor of natural history at Edinburgh, he was appointed director of John Murray's floating marine laboratory (the *Ark*) at Granton, with Hugh Robert Mill as his colleague for hydrographical research. From 1887 until 1897 he was naturalist to the Marine Biological Association of the United Kingdom, being stationed at Plymouth until 1895 and then at Grimsby. He published during this time his monograph on the sole, which remains a standard work, and also his book on "Marketable Marine Fishes", in which much of his own research on the eggs and larvæ of fishes was summarised in convenient form. After serving for a period under the Cornwall County Council as lecturer on fishery subjects, he moved in 1902 to London, where he was engaged in teaching zoology, being from 1917 until 1926 lecturer at East London (Queen Mary) College.

Cunningham was a regular attendant at zoological meetings and frequently took part in the discussions. Although in later years theoretical aspects of biology were his chief interest, he seldom failed to direct attention to significant facts not generally known to his audience which had either come under his own observation or, although recorded, had been forgotten. When the present writer first knew him in 1892 his 'Lamarckian' outlook was already well established and he was always proud of the fact that he had received much help and encouragement in his study of the subject from Herbert Spencer. His own views were summarised in his book "Modern Biology : a Review of the Principal Phenomena of Animal Life in Relation to Modern Concepts and Theories" (1928), and his principal original contributions in "Hormones and Heredity" (1922), and "Sexual Dimorphism in the Animal Kingdom" (1900).

Cunningham was much interested in the experimental side of Mendelian work, as well as in experimental physiology, and always had in hand experiments of interest of his own. So recently as 1930, when more than seventy, he went to Marajo, in the mouth of the Amazon, to study the function of the external filaments which develop during the breeding season on the pelvic limbs of the male lepidosiren ; there he satisfied himself that the observations he was able to make confirmed a view he had previously expressed, that these filaments emitted oxygen to the eggs and larvæ, which develop and grow in the almost oxygen-destitute water in a burrow in the swamp. E. J. A.

Mr. H. W. Clinton-Baker

THE death on April 19, at the age of seventy years, after a few days' illness, of Mr. H. W. Clinton-Baker, the Squire of Bayfordbury, removes a well-known Hertfordshire arboriculturist. Mr. Clinton-Baker will be best remembered for his keen interest in conifers, which he had made the hobby of a lifetime. He became the owner of the Bayfordbury estates in 1903 on the death of his father.

Mr. Baker's love for trees was no doubt inherited from his grandfather, Mr. William Robert Baker, who commenced the famous Bayfordbury pinetum in 1837. The Bayfordbury cedars, planted in 1765 by

an ancestor, Sir William Baker, to commemorate the building of the house, are still among the finest in Great Britain. The pinetum, which at one time contained the best collection of conifers in the country, was considerably enlarged by the late Squire, who from time to time made numerous additions to it. Just before the War he commenced the formation of a new pinetum at Bell's Wood on another part of the estate, which he had planted with conifers recently introduced from China and elsewhere.

Between 1909 and 1913, Mr. Baker's interest in conifers took a more definite shape, when he published three handsome quarto volumes of "Illustrations of Conifers" which contained 'close-up' photographs of all the hardy species in cultivation. The letterpress for the work was prepared by the late Prof. A. Henry and Mr. A. B. Jackson, two well-known authorities on the group. These volumes are a valuable contribution to the literature of conifers, and have been of considerable assistance in the identification of the species. A supplementary volume to the series was commenced some time ago, and will be issued shortly. It is deeply to be regretted that Mr. Baker did not live to see its completion.

News and Views

Iron and Steel

WHEN delivering the Christmas lectures at the Royal Institution in 1925 on "Old Trades and New Knowledge", Sir William Bragg took for the subject of one of his lectures the trade of the smith. One of the objects of this lecture was to show how science has been applied to one of the oldest arts, and what it has revealed. Somewhat the same subject, but under the more prosaic title of "Iron and Steel", and dealt with in a different manner, was taken by Sir William Larke for his Friday evening discourse at the Institution on March 22, and this address is reproduced as a supplement in our issue this week. Within an hour, Sir William reviewed the whole history of the manufacture of iron and steel, pointing out some of the outstanding landmarks, referring to some of the chief inventors and touching upon some of the great achievements rendered possible by the metallurgists.

SINCE iron and steel were first used some thousands of years ago, and since iron was as precious as the crown jewels, many unknown inventors all over the world have added their contributions to the art of iron making, but as Mr. Charles Schwab said, every invention of fundamental importance in the modern iron and steel industry is British in origin. Such names as Darby, Huntsman, Cort, Neilson and Bessemer are well known, and the rise of the iron industry in Great Britain may be regarded both as a cause and a result of the so-called Industrial Revolution. Since the Norman Conquest, said Sir William, there may be said to have been three main phases of industrial development. The first extended to the beginning of the eighteenth century, when power was obtained from animals and men, the second lasted nearly a century and a half and may be described as the age of Iron and Coal, while the third phase, that of the development of metallurgy and alloy steels, has only lasted a quarter of a century, and we may be said to be at the beginning of a new era. Iron manufacture has profoundly influenced the standard of life in the past, and its effect on our social organisation is likely to continue to increase.

Dr. Irving Langmuir, For.Mem.R.S.

THE many friends of Dr. Irving Langmuir will note with pleasure that he has just been elected a foreign member of the Royal Society. It will be remembered (see NATURE, p. 768, Nov. 19, 1932) that he was awarded the Nobel Prize for Chemistry in 1932. In referring to this award, it was pointed out that it is to Irving Langmuir that we owe the conception of the orientated monolayer as the state of material at phase boundaries. A clear and simple interpretation was found for many of the phenomena occurring at interfaces, and new light was thrown on such varied subjects as thermionics, heterogeneous catalysis and surface tension. More recently, Langmuir has been investigating the stability of oil lenses on water as determined by the nature of the monolayer of the interface, a problem with many biological implications. In addition, as the late Sir William Hardy first observed, the orientated monolayer on a metal surface plays an important function in lubrication. During the last two years, Langmuir has also made the important discovery that these layers are destroyed by the passage of a rubbing surface, but if the film be made thick enough, self-repair is effected. Finally, with his co-workers, Langmuir has been investigating the conditions of mobility of substances adsorbed in monolayers on metal substrates, one of the factors to be considered when the rates of catalytic actions are under review.

Prof. Max Weber, For.Mem.R.S.

THE election of Prof. Max Carl Wilhelm Weber as a foreign member of the Royal Society gives well-deserved recognition to one whose influence on biological science is of outstanding importance. After earlier work on Crustacea, Prof. Weber soon entered upon his studies of fish, which were eventually to bring him into the front rank of ichthyologists of the day. His contributions to our knowledge of fish fauna have been very great and resulted from his personal travels into the far north, South Africa and the East Indian Archipelago. The fruits of his researches culminated in his comprehensive joint

work with L. F. de Beaufort on "The Fishes of the Indo-Australian Archipelago" published in three volumes between 1911 and 1916. But to biologists in general, Max Weber is probably better known for his able leadership of the Dutch *Siboga* Expedition in 1899–1900. This expedition covered a distance of about 12,000 sea miles in the different basins of the East Indian Archipelago, and was equipped with the best oceanographical apparatus of the time. The reports of the *Siboga* Expedition edited by Max Weber form one of the major contributions to the science of oceanography, and have filled a large gap in our knowledge of the fauna of that region. Weber himself undertook the study of the fishes collected by the *Siboga* Expedition and published in 1913 his great volume, in which no less than 131 new species were described and 240 species recorded for the first time in the Indo-Australian Archipelago. This work he dedicated to his wife, Mme. Dr. A. A. Weber-van Bosse, who accompanied him on his travels and is herself a botanist of great distinction. Prof. Weber is also the author of the most comprehensive text-book on the Mammalia to be found in any language. The first edition of this work, "Die Säugetiere", was published in 1904 in one volume; the second and latest edition, in two volumes, appeared in 1928. Taking a general view of the work, it is the most complete account in existence of the taxonomy and structure of mammals, living and fossil.

Prof. Moriz Benedikt

PROF. MORIZ BENEDIKT, a leading Austrian neurologist, was born at Eisenstadt in Hungary on July 6, 1835. His medical education was carried on in Vienna, where he studied under Hyrtl, Brücke, Skoda, Oppolzer, Rokitansky and other well-known teachers, and qualified in 1859. During the period 1861–75 he was chiefly concerned with electro-therapy and neuropathology. Afterwards he turned his attention to a comparative anatomical investigation of the brain in man and animals, and craniometric and psychological studies. In 1899 he was appointed professor of neurology in the Vienna medical faculty. In addition to a large number of articles on neuro-pathology, most of which were published in the *Wiener medizinische Presse* between 1869 and 1882, he wrote on anthropology, ophthalmology and otology. Like his contemporary, Charcot, he took a keen interest in art, and a few days before his death, which took place on April 14, 1920, at the age of eighty-five years, published an essay on Raphael. His name has been attached, at Charcot's suggestion, to a syndrome characterised by oculomotor paralysis on one side with paresis and tremor of the upper extremity on the other.

Electrical Units and the I.E.C.

THE practical system of units now in use is consistent, in the sense that the product of a resistance in ohms and a current in amperes gives a potential difference in volts; but it suffers from the defect that the units themselves are not those which would most naturally be derived from the fundamental mechanical units. As a consequence, the product of current in amperes and potential difference in volts gives the power, not in the usual mechanical unit (ergs per second), but in joules per second, that is, in watts. A degree of simplicity is maintained by making the relation between the practical and the absolute unit an integral power of ten in each case. We understand that the International Electrotechnical Commission at its meetings last month adopted the proposals of Prof. G. Giorgi (discussed in NATURE of April 21, 1934, p. 597) to regard these units as derived, not from the centimetre-gram-second system, but from a metre-kilogram-second system. In this system, the unit of velocity is the metre per second, so that the kinetic energy of unit mass (1 kgm.) moving with unit velocity would be 1000×100^2, that is, 10^7 times that of a gram moving with a velocity of 1 cm. a second. Thus the unit of mechanical energy on this system is 10^7 ergs $= 1$ joule, just as in the practical electrical system.

IT is clearly not sufficient to arrange that the product of current and E.M.F. shall give power in watts, but if a further relation is imposed, then the whole system—ohm, volt, ampere, farad, coulomb, henry, joule, watt and weber—becomes definite, and the powers of ten by which these units are related to their C.G.S. counterparts need not burden the memory; they can be recovered at any time by a simple argument. For the additional relation required, Prof. Giorgi assigns the value unity to the present international ohm, and thus makes all the units on his system identical with those of the practical system. An argument in favour of this particular choice, rather than that of current or voltage, for example, is that dimensional formulæ are appreciably simplified if resistance is taken as the fourth independent magnitude, in addition to length, mass and time. The Commission has at the same time endorsed the resolution passed at Oslo in 1930, to the effect that μ_0, the permeability of empty space, should be retained in magnetic formulæ as a physical quantity and not as a mere numeric differing from unity. On the other hand, authors are left free to use the rationalised or unrationalised formulæ, according as the value which they choose to assign to the permeability of a vacuum does or does not absorb the constant 4π.

Archæological Discovery in Crete

A DISCOVERY in Crete, of which the intrinsic interest is enhanced by the recent publication of the concluding volumes of Sir Arthur Evans's "Palace of Minos", in which he deals with the Minoan script, is announced from Athens. A dispatch from the correspondent of *The Times*, which appears in the issue of June 28, states that Dr. Marinatos, director of the museum at Candia, has announced that among antiquities discovered in the Arkalokori district is a copper double axe on which is a three line inscription in characters not previously known in the Minoan civilisation, but bearing some resemblance to those on the famous Phaistos disc. The antiquities with which this inscribed axe was found are dated at about

the sixteenth century before Christ, a period at which the Minoan culture was at its zenith. The discovery is otherwise remarkable in that it includes swords of exceptionally large size, which are said to be greater in number than any other single find of swords ever made in prehistoric Europe. Associated with them were some hundreds of copper axes, a number of silver axes and twenty-seven gold double axes with golden shafts. The claim that the newly discovered script is itself unknown, but bears a resemblance to characters known from the Phaistos inscription, constitutes the chief interest of the find; though it has other points which will intrigue archæologists. In the circumstances, its full publication should be delayed as little as possible, even though this should entail postponement of full discussion.

Soviet Stratosphere Research

IT is learnt from the reports in *The Times* of June 27 and 28 that stratosphere research is very active in the U.S.S.R. It will be recalled that the Russians hold the altitude record of 12 miles for manned balloons made by M. Prokofiev in October 1933, whilst the U.S.S.R. *Stratostat*, which crashed in January 1934, killing its occupants, rose even higher. The present ascent, which was only of 2½ hours' duration, was made from Moscow on June 26, during which time the balloon travelled 100 miles due south. The commander-pilot was M. Kristap Zille, who was accompanied by a physicist, Prof. Alexandre Verigo, of the Central Geophysical Observatory at Leningrad, and a mechanic named Prilutsky. It is stated that during the short flight the altitude reached was more than 9 miles and that the crew landed safely by parachute, apparently as an exercise. Prokofiev's gondola was used, its instruments were landed intact, photographs of the earth were made and varied cosmic ray records taken. It is incidentally stated, though extremely interesting to hear, that the commander had made two other stratosphere ascents in June.

London Transport Scheme

ARRANGEMENTS have been concluded between the Government and the Standing Joint Committee of the London Passenger Transport Board and the main line railways for the development of a transport scheme for London. On June 5, the Chancellor of the Exchequer announced to the House of Commons that a £35,000,000 plan had been concluded. In addition to the extensive schemes included in the Private Bill of the Transport Board, it is intended to electrify the suburban lines of the L. and N. E. Railway in north-east London entering Liverpool Street, and to extend tube railways to give new connexions between these electrified lines and the City and the West End. The high level at which Government credit now stands enables an Exchequer guarantee to be given of loans sufficient to enable the whole undertaking to be started at once. It involves the building of about 12 miles of new tube railways, the electrification of 44 miles of suburban railway and the doubling and electrification of about 12 miles of further suburban railways. In addition, we were glad to learn that trolley buses are to be substituted for tram cars on 148 route miles. These buses, like the cars, are driven by electricity, but they leave the highways more open and much safer for road traffic. It is hoped to complete the works within five years from the date of the loan. Among the improvements, we notice that escalators will be used instead of lifts and will provide ample accommodation for the increased traffic.

Gas or Electricity for Domestic Heating?

THE question of whether to heat our houses by gas or electricity is discussed in an article in the *Nineteenth Century and After* of June by Prof. W. A. Bone. He is naturally proud of the progress made by the gas industry during the past hundred years. He points out that the electrical industry is only fifty years old and has the attractiveness and self-confidence of youth, and so is apt to impress uncritical minds with its superiority. We agree that a London gas consumer buys as much potential heat for 8·6*d*. as would cost an electricity consumer nearly half a crown at 1*d*. per unit. On the other hand, every bit of the electric heat can be utilised, whilst an appreciable fraction of the gas heat passes up the chimney. Electricians are well aware of the relative costs of gas and electricity for heating, and where economy is the primary consideration, water heating by electricity is only advisable in certain cases. We do not agree with Prof. Bone that a chimney is necessary for the suitable ventilation of bed- and living-rooms. Many systems for ventilating rooms have been devised. Possibly in a few years time chimneys will be considered relics of barbarism, and roof gardens will add to the amenity of life. In London, many consumers now get their electricity at 0·5*d*. per unit and are delighted with their electric heaters and cookers, even although they have previously had extensive experience of gas rings and fires. Electricians are continually experimenting, just as are gas engineers; and are remedying some of the defects of the early installations. It is now customary to have the switch for the electric fire about three feet above the floor so that the heat can be regulated without moving an armchair.

Institute of Physics Lectures at Manchester

THE annual lectures on recent advances in physics arranged by the Manchester and District Local Section of the Institute of Physics were held in the Physics Department of the University of Manchester on June 24 and 26. The first lecture was given by Prof. Franz Simon, who is now working at the Clarendon Laboratory, Oxford, and whose researches on low temperatures are well known. He chose as his subject "Low Temperature Research—its Objects and Methods", and gave an account of recent advances in experimental technique whereby temperatures of the order of a fraction of a degree from absolute zero may be obtained. The principles underlying the experimental methods were considered

and reference made to the peculiar properties of certain substances at low temperatures. Prof. M. Polanyi, professor of physical chemistry in the University of Manchester, gave the second lecture, his subject being "Reaction Velocity and Thermodynamics". He discussed the general effect of pressure on the velocity of chemical reactions, using relations deduced in accordance with thermodynamical principles, and referred among other things to the alteration of the equilibrium of reactions due to pressure, the grouping of reactions, and the connexion between reaction velocity and the heat of reaction. He also described recent work on the mechanism of ionogenic reactions. The lectures were well supported by members and friends, and were followed by helpful discussions of the various points raised.

Chemical Industry and Water Problems

THE presidential address of Mr. Edwin Thompson, at the annual general meeting of the Society of Chemical Industry at Glasgow on July 2, dealt with the question of water supply in Great Britain and covered a wide range of topics in that connexion. Mr. Thompson considered the problem of a national water policy to call for immediate investigation. He deplored the spirit of localism which still manifests itself in connexion with every water supply scheme of magnitude, despite the recommendation made nearly seventy years ago by the Royal Commission of 1868 "that no town should be allowed to appropriate a source of supply which naturally and geographically belongs to a town or district nearer to such source, unless under special circumstances which justify the appropriation". He said there is too much selfishness among water undertakings, and that they could do much to relieve the needs of those who have no water supply. He went on to discuss a number of difficulties and problems which are associated with questions of supply: water pollution, rural requirements, misuse and waste of water, the increase during recent years of the *per capita* consumption, diversion of supplies for canals, storage reservoirs, biological factors of storage, sewage effluents into rivers, compensation water, etc. He alluded to and endorsed the necessity for a survey of the water resources of Great Britain and instanced from the report of the British Association Committee the example set in this respect by other nations. The idea of a water grid was dismissed. The valuation of waterworks for rating purposes has a serious financial bearing on the administration and working expenses of an undertaking. The formation of a Select Committee of the Houses of Parliament to go fully into the question of national water supplies made him confident that the anxieties and hardships of the past year will never be repeated.

The Annual Tables of Constants

AT the conference of the International Union of Chemistry, held in April 1934 in Madrid, it was recommended that a substantial part of the funds at the disposal of the Union should be transferred to the International Committee of Annual Tables of Constants, in order to assist in the publication of these valuable tables. This recommendation was passed unanimously by the Union's executive in Paris in last October and confirmed by the national organisations representing the various countries adhering to the Union, such as Verband Deutscher Chemischer Vereine representing Germany, Comité National Belge de Chimie representing Belgium, National Research Council, Division of Chemistry, representing the United States, and so on. The sum thus put at the disposal of the Committee of the Annual Tables is 150,000 francs; the amount indicates the importance which international chemical circles attach to the continuation of the Annual Tables. This sum will be used up for printing the index of the second series (vol. 6–10, 1923–1930), which is now ready. In return for this gift, the Committee of the Annual Tables is going to put at the disposal of the chemical organisations adhering to the Union a certain number of complete sets of the Tables.

Atmospheric Pollution

THE twentieth report on atmospheric pollution issued by the Department of Scientific and Industrial Research (H.M.S.O., 5*s*. net) records observations for the year ending March 31, 1934. This report, like its forerunners, shows that preconceived notions are not always supported by measurement. If the conditions of sampling and test are valid, then the City of London has the most polluted atmosphere observed in Great Britain, and deposits of solids and tar show annual increase. Again, foggy weather, judged by measurement of 'smoke haze', appears to reach greatest prevalence in Westminster, and some of the highest figures for sulphur pollution are also found in London observing stations. Some so-called industrial cities apparently have atmospheric conditions much superior to those in London. London may, however, take comfort from the fact that comparable measurements show that atmospheric pollution in Philadelphia is almost twice as bad. Experience is recorded with the use of a 'candle' of lead dioxide for measuring atmospheric sulphur compounds. Another interesting apparatus has been devised for recording the quantity of light. The light received by a photo-electric cell develops a current which imparts to a condenser a charge. When this reaches a certain amount, it discharges through a neon lamp and causes an ordinary counter to advance one unit. The difference between the records at the various stations is great, and it may be inferred that large improvements in atmospheric conditions are possible by using experience already known.

Epidemic of Green Fly

WE learn from the Ministry of Agriculture and Fisheries that, in many districts in the southern half of England, oats have suffered from severe infestations by aphides or 'green fly'. Similar attacks on grassland have taken place in certain northern counties, including Lancashire. The insects occurred often in swarms, smothering the crops and causing

much damage. The species concerned is a common one which often causes local and temporary injury to grass. Its appearance in epidemic form on cereals is quite unique in recent times. The reasons for the outbreak are unknown, but they are probably associated with the relatively mild autumn and winter and the advanced condition of the crops. The standard control method would be the application of an insecticidal dust by means of a powder sprayer. The necessary equipment, however, is not available on many farms, and expenditure to meet this treatment seems scarcely justifiable in view of the damage that has already been done. It is probable that the aphids will shortly migrate, while natural enemies are already actively at work.

Metals in Food

THE Society of Public Analysts has issued a useful "Bibliography of the More Important Heavy Metals occurring in Food and Biological Material", the period covered being the years 1921–33. The elements dealt with are antimony, bismuth, cadmium, chromium, cobalt, copper, lead, manganese, mercury, nickel, thallium, tin and zinc. Each reference indicates the nature of the information to be found in the paper. The largest sections deal with copper, lead and manganese, which account for half the references quoted. The pamphlet (30 pages) can be obtained from the Editor of the *Analyst*, 85 Eccleston Square, London, S.W.1 (2*s*. to members of the Society; 3*s*. to non-members).

Principles and Design of Precision Gauges

IN these days of motor-cars, electric fittings and so on, everyone learns something of the value of interchangeability of parts and also experiences the disadvantage of finding that a part 'will not fit'. The progress of manufacture, indeed, depends largely on parts being interchangeable, and in mass production it is absolutely necessary to place limits on the permissible variation from standard dimensions. This necessity has given rise to the system of working to gauges, a system which received a great impetus through the manufacture of vast quantities of munitions during the War, and which to-day is perhaps used most extensively in the manufacture of motor-car engines and other parts. From being a comparative novelty, gauging has become a matter of ordinary routine, while the making and testing of gauges has itself become an industry. There will thus be many persons who will be able to appreciate the pamphlet of Mr. R. J. Foster on "The Principle and Design of Precision Gauges for Interchangeability" recently issued by the Association of Engineering and Ship-building Draughtsmen, and published by the *Draughtsman* Publishing Co., Ltd. (2*s*.). In this the reader will find sections on tolerances and fits and limits, plug gauges, pin gauges, external and internal gauges, height and depth gauges and comparators, together with many sketches and useful notes.

International Geological Congress

PRELIMINARY arrangements are announced from Moscow for the meetings of the Seventeenth International Geological Congress, which is to be held in the U.S.S.R. during the summer of 1937, the year of the twentieth anniversary of the Soviet Government. It is proposed that the first half of August should be devoted to the sessional meetings. The special topics suggested for discussion include petroleum, coal, ore-deposits, rare elements, geophysical methods, the Permian system, tectonic and geochemical problems, the relationship of magmatic rocks and ore-deposits to tectonics, and the history of geological knowledge. Three series of excursions, *A*, *B* and *C*, are provisionally arranged, to take place respectively before, during and after the sessions, the whole programme extending from the beginning of July to the end of September. The *A* series includes excursions to the north (Pre-Cambrian and Khibina Complex); the Urals; the south (Crimea and Donets Basin); the Volga Basin; and the Caucasus. The *C* series are on a larger scale and cover very wide regions. They are described as petroleum and stratigraphical (main oil districts and Central Asia); Central Asia (stratigraphy, tectonics and volcanic phenomena; transcontinental (stratigraphy, tectonics and economic geology of Urals to Soviet Far East); and Turkestan-Siberia (Perm, Altai and Kuznetsk). More detailed descriptions will be given later. Meanwhile inquiries are invited and should be addressed to the Organisation Committee of the Seventeenth International Geological Congress, Moscow, 4, Kotelnicheskaya, Naberezhnaya, 17.

A Recent Sunspot

A FAIRLY large group of sunspots has recently been visible whilst crossing the sun's disc on June 23–July 6 in long. 305° and lat. 24° S. Its area on June 28 was 1000 millionths of the sun's hemisphere, of which 850 millionths was the area of the leader spot. When near central meridian passage, which occurred on June 29·9, the group was visible to the naked eye. Though itself not a return of an individual spot of the previous rotation, the recent spot represented a continuation of localised disturbance which has been apparent for the last two months in this part of the solar surface. In an ordinary telescope, the group has been an interesting object with conspicuous 'bridges' across the leader spot in particular. The spectroscope offered, as usual, a further range of observation. On June 26 at $8^h\ 45^m$ G.M.T. a bright eruption took place that was observable visually in the hydrogen *C* line of the solar spectrum and should have been possible to photographic records in the *H* and *K* lines of ionised calcium. The spectrohelioscope showed with perfection the contour of the areas of the brilliant hydrogen (Hα) emission and the dark filaments of gas bordering them at a later stage. The largest radial velocities measured at Greenwich for the absorption filaments were 20 km. a sec. outwards and 60 km. a sec. inwards to the sun. On June 29 at about $8^h\ 45^m$, several moderately large radial

Supplement to "NATURE"

No. 3427 SATURDAY, JULY 6, 1935 VOL. 136

Iron and Steel*

By Sir William J. Larke, K.B.E., Director of the British Iron and Steel Federation

NO single element has exercised such a profound influence on the social organisation of mankind as iron. To-day, directly or indirectly, it enters into every moment of our lives, sleeping or waking; the production of our food, our clothing, our homes, our furniture; and without it modern transport by sea, land and air, the distribution of gas, water and electricity, in fact all the amenities of modern civilisation, would be impossible. We are still in the Iron and Steel Age, and likely to become more and more dependent on them for our material well-being.

Fortunately Providence has ordained that 4·44 per cent of the earth's crust consists of iron in various forms. Though widely scattered, it is found in varying degrees of richness in iron content from a trace up to 60–70 per cent. It is usually only described as iron ore when the iron content is at least 20–30 per cent, as the iron is too costly to extract with smaller content. A feature of all early iron production, owing to the difficulty of obtaining a high temperature, which in primitive furnaces seldom exceeded 1,100° C., was the use of iron ore or sand of high iron content, a fact which limits the area likely to have given birth to the iron culture.

The qualities of iron were aptly described by Dr. Ure in his "Dictionary of Arts and Manufactures". "Every person," he says, "knows the manifold uses of this truly precious metal. It is capable of being cast in moulds of any form, of being drawn out into wire of any desired strength or fineness, of being extended into plates or sheets, of being bent in every direction, of being sharpened, hardened or softened at pleasure. Iron accommodates itself to all our wants, our desires, and often our caprices. It is equally serviceable to the arts, to science, to agriculture, and the same ore furnishes the sword, the ploughshare, the cannon and the bomb. It is a medicine of much virtue and the only metal friendly to the human frame. The ores of iron are scattered over the crust of the globe with a beneficent profusion proportionate to the utility of the metal; they are found under every latitude and every zone, in every mineral formation and are disseminated in every soil."

Iron beads and other articles have been discovered under conditions indicating that iron was known as a precious metal in Egypt at least 4,000 B.C. A sickle blade found by Belgoni under a sphinx at Karnac, and a portion of a cross-cut saw found in one of the pyramids by Colonel Vyse, estimated at 3,000 B.C., are the earliest evidence of its use for purposes other than ornamental. Such early iron has been proved to be of meteoric origin, and indeed the word iron in most cultural languages is derived from a root meaning 'something hard from the sky'. This acceptance of its origin was very widespread. According to Zimmer and others, de Cortez, whilst in Mexico in 1519–21, found that the Aztecs possessed knives and daggers of iron, which were prized higher than gold, being of great rarity; but they had no knowledge of how to smelt it, and when asked, stated that the material came from the sky.

Zimmer in his paper on meteoric iron points out that as meteoric iron contains 3 per cent of nickel, the ancients possessed a steel which (when they were fortunate in the mass they used, as it was of very unequal constitution) was not available to mankind by a manufacturing process until 1890. He points out that 99 per cent of the then (1916) known mass of about 250 tons of meteoric iron is ductile. It was not, however, until a famous fall of meteorites was witnessed at L'Aigle in Normandy on April 26, 1803, by thousands of people, that the celestial origin of meteoric iron was generally accepted in modern times. Such iron contains iron, nickel, copper, cobalt, phosphorus, and in most cases in addition sulphur, carbon and silicon, so that it is a highly complex alloy. There is little doubt that all the early iron in North America up to the fifteenth century was meteoric in origin. Man doubtless discovered the existence of terrestrial iron through the accidental fusing of ore in a camp fire, but there is no evidence to show at what date.

* Friday evening discourse delivered at the Royal Institution on March 22.

Earliest remains indicate that the smelting of iron was known in India approximately 1,400 B.C.; and the discoveries at Hallstatt in Styria and Carinthia (the Roman Noricum), in the famous cemetery, where some thousand graves have been investigated, fixes the date of a highly developed iron culture at approximately 1,200 B.C. The importance of the Hallstatt finds is that examples of bronze and iron weapons found side by side, exactly the same in shape and design, show they were made in a transition period from the Bronze to the Iron Age. Dr. Percy in his great work on metallurgy pointed out that the Iron Age must have preceded the Bronze Age, since it was obviously easier for primitive man to have smelted iron than to have made an alloy of copper and tin; but it is suggested that bronze was almost certainly the result of the smelting of an ore of copper and tin found in the same mine, and that the alloy was not until later a controlled mixture.

The evidence in favour of either centre, Europe or Asia, as the birth-place of iron smelting is of necessity speculative. It is significant that both iron and steel are indiscriminately referred to by ancient writers in describing the material, and there is no doubt that, in the early processes of smelting, iron of varying degrees of hardness and varying qualities was produced.

Early remains indicate that the first iron furnace consisted of a hole in the ground lined with clay, in which were set alternate layers of charcoal and iron ore. The product was a mass of spongy iron mixed with slag and charcoal, which had to be reheated and hammered to eliminate the impurities and render the metal fit for forging into weapons and tools. The resulting metal was no doubt soft, and it is recorded of some of the ancient tribes who were iron workers, that when fighting the Romans, who were then armed with bronze, their weapons frequently bent and required to be straightened.* The production of steel of a high quality under controlled conditions seems to have been established in India several centuries before the Christian era.

According to Colonel Belaiew, wootz, the steel from which the famous Damascus swords were made, was produced by a crucible process. The spongy mass of iron produced from the furnace was broken up, remelted in a crucible with charcoal, allowed to cool, and then reheated and hammered several times; finally being hammered into small cakes about 5 in. in diameter and $\frac{1}{2}$ in. thick, called wootz, which was then an article of merchandise carried from India to Damascus and to Toledo in Spain. This process produced a beautiful steel for the purpose, which, when etched with acid, developed a blue watermark known as Damascening. Its constitution was a eutectoid steel of approximately 0·9 per cent carbon, containing segregations of glass-hard carbide of iron, cementite (Fe_3C), which in the process of production had become spheroidal. The steel gave the swords remarkable flexibility when tempered, and the glass-hard spheroidal particles of cementite took and retained a very sharp edge.

Between the soft weapons of the early Iron Age in Europe and the more highly finished steel of the early productions of India, there is the complete range of qualities in iron and steel which ultimately led to the transition from the Bronze Age to the Iron Age. The hard bronze weapons of the Romans were at least a match for those of soft iron produced directly from the ore; but as the production of steel became more general, the steel weapons were able to pierce bronze armour. The importance of iron for weapons was recognised by the Etruscan King Porsena, 507 B.C., who in the conditions of peace prohibited the Romans from using iron, except for agricultural purposes. It seems evident that iron and steel weapons displaced bronze after Marathon, approximately 490 B.C. About the same period the Phœnicians established colonies in Spain and introduced iron making as followed by the Greeks, and during the second century B.C. Spain became the greatest iron centre, and remained so for centuries. The Romans during the second century B.C. adopted Spanish swords, and Toledo blades were famous long before the Christian era. There was a great belief at this period in the efficacy of the qualities of certain waters, particularly the River Salo in the north of Spain, for tempering—a belief that has been revived even in modern times, when competitors of Sheffield have attributed qualities to the local water which were the result of the abilities of the local people.

Although examples of the Hallstatt iron weapons have been found in Great Britain, and according to Ault were the cause of the people turning their attention to iron, the Iron Age seems to have commenced here about 400 B.C. The iron mines of Sussex were famous until the eighteenth century. The advent of iron tools for wood working and for agriculture converted man from a hunter to a farmer, and thence to a capitalist as he accumulated at first stores of grain, and then more and more tools. It was at this stage that iron assumed its first economic importance. From this period until the eighteenth century its influence and importance with regard to social and economic development was of the same character, though increasing in degree. The furnaces in which the ore was smelted with charcoal, consisting of holes in the ground with goat skin bellows, gave way to structures reared above the

* Polybius's account of Addua 223 B.C.

ground, in which were inserted tubes or tuyeres for the blast. These structures were called bloomeries, from the Anglo-Saxon *bloma*, a lump. They were adopted by the Romans and ultimately used with water-driven bellows, and hammers for *forging* or *refining* the iron. This method of production continued well into the seventeenth century.

During the period of the modern history of England, that is, from the time of the Norman Conquest, there may be said to have been three main phases of industrial development. The first and longest phase lasted until the early part of the eighteenth century, being the era in which physical force was only obtainable from the strength of horse and man. It was the era in which the influence of iron became important as an adjunct to wood, in forming the manual tools for agricultural and structural purposes. The second industrial phase lasted nearly a century and a half, and may be described as the age of iron and coal; while the third phase, that of the development of metallurgy and alloy steels, has only lasted a quarter of a century, and we may be said to be at the beginning of a new era.

In the seven centuries of the first period, iron was too costly for general use, except in a very limited way, and its main use was service in war. But so early as the ninth century, the iron horseshoe had been introduced—an invaluable adjunct, which not only adapted the horse to work in regions other than grass lands, but greatly increased his effective pulling power.

The large-scale development of the use of iron, even in the form of manual tools, was delayed due to the difficulty of producing it.

While copper can be melted at a temperature of 1,100° C., and some of the bronzes at a much lower temperature, it requires at least 1,600° to melt steel. Until the difficulties involved in producing material at such a high temperature on a large scale were finally solved, the use of iron was confined to the most essential needs of agricultural implements and arms. At the same time, it must be recognised that, except as a means of improving the efficiency of manual tools and producing them in greater quantity, the need for large-scale production had not arisen and could not arise until the advent of the Machine Age in the eighteenth century.

Cast iron was not used in Europe until about 1340. In the reign of Edward III, iron was of such importance that an act was passed prohibiting the export of any iron, whether made in England or previously imported, under penalty of forfeiting twice as much to the king as was taken out of the country. According to Parker, the iron pots, spits and frying pans were classed among the Crown jewels.

Cast iron was largely used for cannon and cannon shot, which were exported from Ilsenberg in Germany in the fifteenth century; iron stoves were cast in Alsace in 1490. A small iron industry grew up in the wealds of Kent and Sussex, where iron ore and timber were both available; but it gradually acquired a national importance with the advent of cast iron in the sixteenth century, and became notable for the production of cannon which were exported to other countries. In fact, complaint was made that British cannon were used against England in the wars with Spain in the sixteenth century.

Generally it may be said that the iron industry had for some centuries exercised great influence on the development of civilisation. So far as it gave predominance to any particular people over others, it was mainly in the production and improvement of arms and agriculture. Having regard to its limited use, the industry had reached a considerable magnitude in England in the sixteenth century. As timber was urgently required for shipbuilding, legislation was enacted, restricting the production of iron and encouraging its importation. This was so effective that, while there were 300 furnaces recorded in England in 1665, these had been reduced to 59 by 1740. In 1750 a petition was made to Parliament by the tanners of leather in and about the town of Sheffield in Yorkshire, against the bill encouraging the importation of iron from the American colonies, on the grounds that if English iron were not produced, the tanners would be deprived of the oak bark, which was stripped from the oak before it was converted into charcoal.

Thus even towards the middle of the eighteenth century the iron industry in Great Britain was a decaying one, iron and steel being largely imported from Europe and the American colonies. But at this time commenced the most remarkable development of our material civilisation. Abraham Darby at Coalbrookdale had been experimenting with the use of stone coal in the production of iron, owing to the limitations of the use of charcoal. In 1735 he used coke in the blast furnace, and this date marks the birth of the modern iron and steel industry. The blast at this time was still created by the use of bellows driven in many cases by a water-wheel. Dud Dudley had claimed to have smelted iron with stone coal in 1620, but never brought it into general use (see NATURE, 134, 842; 1934.)

The scale of the industry in England may be gauged from the fact that the total production of iron in the year 1740 was only 17,350 tons, which was the second highest production of any country in the world, Sweden then being the highest, owing to her large resources of timber.

This has enabled Sweden to-day to maintain her supremacy in the production of charcoal iron. She possesses no natural supply of stone coal.

Darby's use of coke for smelting instead of charcoal gradually spread over the whole country, and by 1760 was common practice. This had the effect of transferring the iron industry from the wooded districts of the wealds of Surrey, Sussex and Kent, immediately to the Black Country, and finally to the other coal districts of South Wales, the north-east coast of England and Scotland. The full advantage, however, of Darby's method could not be obtained by the inefficient water-driven bellows then available. By a remarkable coincidence, Watt developed his improved steam engine in 1769. This development was facilitated by the improved production of iron by Darby, but Watt's engine made available to the iron industry vastly increased blowing power, thus increasing the possible temperature in larger furnaces, and modern blast furnace development became possible.

The blast furnace is the most economic means of extracting iron from its ores. The iron is contained in the form of oxides, or in some cases of carbonates, mixed with a gangue material consisting mainly of silica. The furnace is charged with iron ore, coke and in most cases, depending on the nature of the materials used, limestone. The iron oxide is reduced chiefly by the gas passing upwards through the furnace, which contains carbon monoxide produced by the introduction of hot air at the bottom of the furnace. The lime produces an easily fusible slag with the gangue materials of the ore and, as the materials pass by gravity through the furnace, they reach the hearth at the bottom in a molten state where they separate naturally into two layers, the lower being molten pig iron and the upper slag. The final elimination of the oxygen contained in the iron takes place in the hearth. Two tap holes are provided in the hearth, one above the other. From the upper, slag can be withdrawn, and the pig iron flows by gravity from the lower. The iron thus produced contains about 4 per cent of carbon, varying proportions of silicon, and small percentages of impurities such as sulphur and phosphorus, depending upon the ore used or purpose for which the iron is required. Other elements may be introduced, if required, by including suitable materials in the burden charged at the top.

Blast furnace practice has been enormously improved, but the fundamental principles remain identical with those which have characterised the production of cast iron since the fourteenth century, the earliest period in which it was known. But whereas a single furnace could only produce, even so late as the end of the seventeenth century, less than 200 tons a year, and the average output of the charcoal furnace in 1806 was of the order of 700 tons a year, the coke furnaces were by that time producing approximately 1,700 tons a year. The average production of the blast furnace to-day in Great Britain is 60,000 tons a furnace a year, and there are single furnaces in operation producing 4,000–5,000 tons a week. There are some on the Continent, and in India, producing nearly twice as much as this.

The size of the blast furnace is governed to-day by the market requirements of the resultant product, and in Great Britain—the birth-place of the modern iron and steel industry—there is still made a wider diversity in qualities of iron and steel products than in any other country in the world. The volume of production in Great Britain is now the fourth highest, but is still only one quarter in volume of the normal production of the United States.

It should be mentioned that the most important results of the technological improvements in the blast furnace have been the reduction in the quantity of fuel required. The invention of the hot blast by Neilson in 1828 in Scotland reduced fuel consumption from more than 8 tons of coal to 5 tons per ton of pig iron produced, and by 1840 the average quantity had fallen to 3½ tons, but very much lower in many furnaces. The consumption in modern practice depends on the nature of the ore used, and particularly its iron content; but under suitable conditions with suitable materials, 1 ton of pig iron has been produced with a consumption of 15 cwt. of coke (equivalent to say 22 cwt. of coal).

Referring to the enormous increase in the capacity of blast furnaces, it should be noted that in 1878, when the average annual production of pig iron per furnace in Great Britain was approximately 6,400 tons, there were 948 furnaces, whereas to-day there are actually only 96 in blast with an average production of 60,000 tons a year. So late as 1920 there were 481 furnaces in existence, 284 in blast, with an average annual output of 28,000 tons.

It is not an exaggeration to say that the Machine Age and the Industrial Revolution owe their birth to the inventions of Darby and Watt, since by making iron much more readily available, the inventions of that very remarkable period of 150 years from the middle of the eighteenth to the end of the nineteenth century were made possible which resulted in the replacement of handicraft by machines, and revolutionised production.

The production of individual industries rapidly increased with the application of the steam engine and machinery beyond the absorptive capacity of accessible markets, in view of the limitation of transport. Thus, on the introduction of railways in 1825, there existed a surplus of production in

many centres of the country, awaiting distribution. It was the fact that industrial production had overtaken the immediate consuming power of the communities accessible to the producers that created for the railways such a period of feverish activity and prosperity.

The construction of the railways absorbed the greater part of the iron and steel production, even up to 1881. In that year, out of the total production of steel in Great Britain of 1,778,000 tons, 1,000,000 tons was used for rails alone, and in the United States, which in the same year produced 1,000,000 tons of rails, the total steel production was only 1,588,000 tons.

Early railway development was based entirely on iron. While the development of the rail track had passed through the stage of a flat timber wagon way with flat wheels, followed by an edge rail in timber, in the later stages covered with iron, with flanged wheels, it was not until Jessop introduced the edge rail, which consisted of cast iron rails 3 ft. long by 1½ in. with a raised head and flanged wheels, in 1790, that the modern railway track may be said to have been born.

It is of interest to note how the use of iron has passed from what might be termed wrought iron in the prehistoric and early historic period, to the more frequent use of cast iron, particularly after the advent of Abraham Darby. It was not until 1784, with the invention by Cort of the grooved rolling mill for rolling iron bars, and of the puddling furnace for converting cast iron into what is now called wrought iron, that the forged material again became of prime importance.

In 1805 wrought iron rails were produced 15 ft. in length, which was a great advance over the cast rails, which could only be made at that time about 4 ft. long. Wrought iron takes its name from the fact that the iron is refined in a plastic state and never allowed to become molten, the grains of iron being welded and wrought into shape by a kneading process, either that invented by Cort of puddling pig iron, or by direct reduction from the ores, the resultant spongy mass being frequently hammered and reheated to eliminate slag and ash, as in ancient times.

The Delhi Column is perhaps the most remarkable example of ancient wrought iron extant. It was erected by the Majaraiah Dhava about A.D. 320. This column weighs 6½ tons, and is 24 ft. long, 16½ in. in diameter at the foot, and 12½ in. at the top. A sample of the material has been analysed by Sir Robert Hadfield, and proved to be iron of an extraordinary high purity—no less than 99·72 per cent. The means by which so massive an object, of a material of such high quality, could have been produced 1,600 years ago are still a matter for conjecture.

The metal part of wrought iron is pure ferrite crystals. Interspersed between them are minute threads of slag. Slag is not in this case an impurity, because it confers upon wrought iron its powers of resistance to corrosion. Wrought iron is easily forged, and has been used for some of the most important structures in the world, notably the two bridges over the Menai Straits, Telford's suspension bridge in 1825 and Stephenson's tubular railway bridge, 1850. The latter consists of two wrought iron tubes each 1,510 ft. long. As a testimony to the resistance to corrosion of wrought iron, it may be mentioned that only a few links of the suspension bridge have needed to be replaced, and none of the plates of the two tubular tunnels. The weight of wrought iron in the tubular bridge is 10,540 tons, a very remarkable structure, having regard to the period in which it was erected.

At about the same period Robert Stephenson built the high-level bridge at Newcastle across the Tyne. This is one of the largest cast iron structures in the world. It was opened by Queen Victoria in 1849, and carries both road and railway. The total length of this bridge is 1,337 ft. It is 112 ft. above high-water to rail-level. There are six spans of 125 ft. each and the lower roadway is 22 ft. 7½ in. below the rail-level. The total weight of iron used is 5,050 tons and the total cost was £243,000. Cast iron is still an important structural material; the tunnels of the tube railways and the Mersey tunnel are lined with cast iron sections; no less than 80,000 tons of cast iron were used in the construction of the Mersey tunnel.

In 1850, steel was only made in small quantities in crucibles or by cementation, which were long and costly processes. According to Bessemer, this steel, when rolled into bars, was sold at £50–£60 per ton. He desired to produce a metal having the mechanical characteristics of wrought iron, which could be run into an ingot mould in fluid condition. After years of experiment, he finally developed the process associated with his name, the decarburisation of molten iron by blowing air through it in a vessel called a converter.

This invention by Bessemer marked the birth of the modern Steel Age, as it made steel available in quantities much greater and at a cost much lower than was possible in the case of wrought iron. For many purposes steel immediately proved a superior material, being harder to wear and stronger mechanically. It could also be cast, rolled and forged and was thus able to meet all the demands of the engineers in its application to the production of structures and machines. The first Bessemer steel rail was rolled at Dowlais, Glamorgan, and laid on the main line of the

Midland Railway at Derby in 1857, and it proved to have some twenty times the wearing life of existing iron rails.

About 1860 Siemens developed a regenerative furnace in connexion with glass-making. Faraday delivered one of his last lectures in the Royal Institution in June 1862 on the simplicity, power and economy of the regenerative open hearth furnace, but it was not until 1865 that the first experimental plant was erected by Sir William Siemens at the Sample Steel Company, Birmingham, and the furnace for making steel was put to commercial use.

The open hearth Siemens-Martin process was developed by Siemens and Martin in 1864–67. It had the great advantage over the Bessemer process that, whereas the refining in the latter took 20–30 minutes and the degree of refinement was a matter of empirical judgment, in the case of the open hearth process the time required was at least eight hours and the degree of refinement and quality of the product could be tested by means of samples during the process. The result was that a more consistent quality of product was obtained, and the open hearth process ultimately displaced the Bessemer process in Great Britain.

It is interesting to note that with improvements in the process and particularly the control of the qualities of pig iron, which is the key to the control of the quality of the resultant steel, the Bessemer process is again being used for many purposes in Great Britain. For the past fifty years it has been supreme on the Continent.

The next great advance in steel production was the invention by Sydney Gilchrist Thomas in 1877 of the basic process. Thomas originally intended to be a doctor, and was preparing for his matriculation at the age of seventeen years, when his father died. He was thrown on his own resources and accepted a junior clerkship at Bow Street at a salary of £90 a year. He devoted his spare time to the study of science, principally chemistry. Mr. Challenor, in a course of lectures at the Birkbeck Institute in 1870, said: "The man who eliminates phosphorus by means of the Bessemer converter will make his fortune." This fired the imagination of Thomas. Working under great disadvantage in co-operation with his cousin Gilchrist, who was a chemist in a works in South Wales, they ultimately succeeded. His paper on the process, however, in 1878, before the Iron and Steel Institute, was actually not read for lack of interest until an adjourned meeting in 1879. However, this invention was taken up in that year by Messrs. Bolckow Vaughan, of Middlesborough, who were already producing steel by the original acid Bessemer process and desired to use the Cleveland ironstone which was not suitable for that process, but the use of which was rendered possible by Thomas's invention.

It should be stated that the acid process does not eliminate the sulphur and phosphorus from the iron. For this reason the materials charged must be of a high degree of purity, particularly with regard to sulphur and phosphorus content, as these two elements have a deleterious effect on the quality of the finished steel. The materials charged may be either pig iron or steel scrap of suitable quality, or both. The basic process, as invented by Thomas and Gilchrist, removes phosphorus through the action of a basic slag largely consisting of lime, and the sulphur partly by the slag and partly by the action of manganese contained in the basic pig iron. When the steel has been cast from the furnace into the ladle, any residual oxygen is removed by the addition of aluminium or some similar suitable reagent. If decarburisation has been carried out to a greater degree than is required, the carbon content may be brought up to the required figure by the addition of anthracite in the ladle; also other elements as may be required are frequently added in the same manner.

By far the most important immediate result of Thomas's invention was its adoption on the Continent, as it rendered possible the use of the large deposits of high phosphoric ores in Alsace and Lorraine. The result has been the application of the basic process to open hearth practice and the consequent enormous increase in the production of steel throughout a large part of the civilised world, as can be seen from the growth of world production, with a rapidity which has had an influence, the importance of which can scarcely be exaggerated, on the development of population and improvement in the standard of life.

United Kingdom and World Production of Pig Iron and Steel 1835–1934
(in millions of tons)

Year	Pig Iron		Steel	
	World	U.K.	World	U.K.
1835	1·88	1·00	—	—
1845	2·95	1·51	—	—
1855	5·06	3·22	—	—
1865	8·97	4·82	—	—
1869	11·10	5·45	0·42	0·16
1875	13·61	6·37	1·79	0·71
1885	19·33	7·42	6·19	1·89
1895	28·50	7·70	16·65	3·26
1905	53·24	9·61	44·22	5·81
1915	59·70	8·79	65·57	8·55
1925	75·69	6·26	88·93	7·39
1929	97·35	7·59	118·37	9·64
1931	54·73	3·77	68·07	5·20
1932	39·69	3·57	50·11	5·26
1933	48·77	4·14	65·74	7·02
1934	61·34	5·98	78·93	8·86

It is interesting to compare the growth of population in relation to iron and steel production. From 1066 until 1760 the population of England and Wales increased by some 5½ million, considerably

less than one million per hundred years, while in the next hundred years it increased by 13 million. Similarly, iron production increased slowly from possibly a few hundred tons in 1066 to about 50,000 tons in 1760, and then rose rapidly to nearly 4 million tons in 1860. The rapid expansion of iron production not only coincided with, but also may well be said to have made possible the rapid growth of population. It is interesting

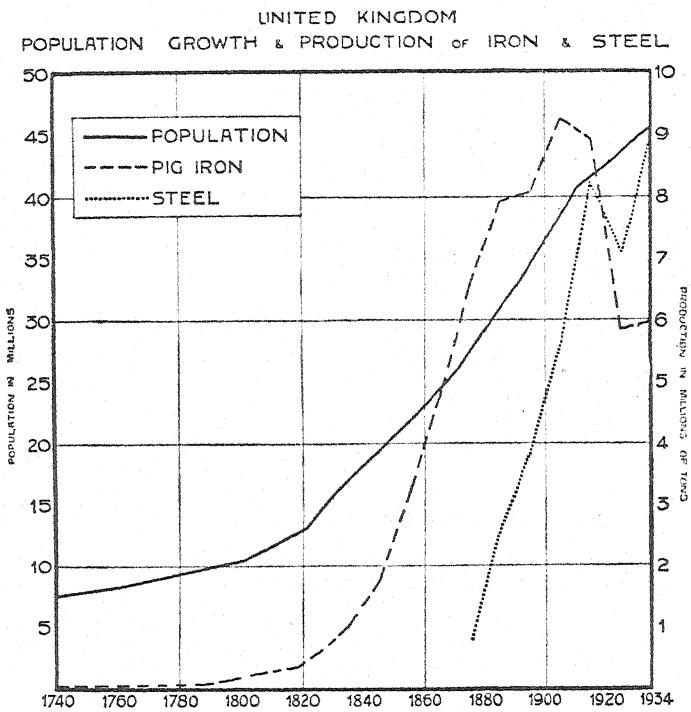

FIG. 1.

to note that the iron output increased much more quickly than the population. Too much significance must not be attached to the relation of these curves, but their general trend shows the paramount influence of the development of iron and steel on population (Fig. 1).

The invention of the basic process was one of the greatest fundamental inventions. Mr. Chas. Schwab, president of the American Iron and Steel Institute, has pointed out that every invention of fundamental importance in the modern iron and steel industry is British in origin, as may be seen from the accompanying table of notable dates:

NOTABLE DATES IN THE IRON AND STEEL INDUSTRY

Payne and Hanbury produced tin sheets, Pontypool	1728
Abraham Darby first used coke in blast furnace	1735
Huntsman produced crucible steel	1740
Smeeton invented blowing cylinder	1760
Watt improved steam engine	1769
Cort grooved rolling mill	1783
Cort puddling furnace	1784
Stevenson's locomotive	1815
Stockton Railway	1825
Neilson invented hot blast	1828

In the third phase of our material civilisation, to which I have referred, and of which we are only in the first quarter-century, we are experiencing a revolution as a result of the application of scientific discovery, which has produced materials possessing qualities as to resistance to corrosion and stress undreamt-of even in the nineteenth century.

In 1832 Faraday, who certainly by his discoveries exercised a wider and more far-reaching influence on our modern civilisation than any other single man, discovered that the resistance of a metal to oxidation was due to the existence of an oxide film which formed on the surface. It was not until nearly a hundred years later that this was conclusively demonstrated by Dr. Ulick Evans in his beautiful research work at Cambridge, by which he succeeded in actually removing the film and examining it microscopically. Faraday had experimented, 1819–24, with a number of alloys of iron with other metals, and was the discoverer of the enormous potentialities of alloy steels. The scope of Faraday's work in this direction was not generally realised prior to Sir Robert Hadfield's examination of the specimens in the possession of the Royal Institution.

The influence of chromium alloyed with iron in facilitating the automatic production of the protective film was first brought out by Monnartz in 1911. The industrial development of this phenomenon can be traced to the research of Mr. Harry Brearley in the Brown-Firth Laboratories, who found that the resistance of iron chromium alloy to nitric acid was increased as the percentage of chromium was increased.

After a long research investigating the limiting ranges of composition giving high resistance to corrosion, Mr. Brearley developed the well-known stainless cutlery steels, containing about 0·3 per cent of carbon and 12–14 per cent of chromium. The rustless steels now available industrially are either chromium-nickel steels or chromium-nickel steels to which other elements such as manganese and silicon have been added.

The variations of this class of steel and the qualities and purposes for which they are used require an exhaustive study in themselves. They are applied to all uses where super-corrosion resistance is necessary, that is chemical plant, aircraft fittings when exposed to the action of acids, manufacturing machinery, general engineering where resistance to abrasion is required or a good cutting edge is necessary. They are largely used in food manufacturing, chemical and textile industries,

but it is obvious from their constitution, in view of the value of chromium which they at present must contain, that they are unlikely, in spite of their high mechanical qualities as regards tensile strength and yield point, to be used for general structural purposes.

There is another entirely different class of steel, which is still made by the crucible process, of which Sheffield is the centre, and of these varieties and qualities and the service for which they are used, the number is legion. One maker since 1860 has produced steels of this quality to more than twenty thousand different analyses. The products vary in value from £45 a ton to more than £800 a ton, and when converted to tool steel, are sold at a price which works out at £840 a ton. In a works of this character, instead of the output being measured in figures of the order of 3,000–4,000 tons a week with 12–20 different sizes and as many different qualities, the production in a typical week was 50 tons with 135 different sizes and 109 different qualities. Hair-spring wire reduced to 9/1,000 in. diameter from a 4 in. diameter ingot, which is drawn through a diamond die in its last stages, has a value of 16*s*. a pound or approximately £1,800 a ton. Ordinary structural steel has a selling price of approximately £8 a ton.

These high-grade steels are used not only in engineering trades, motor cars, aeroplanes, but also by watchmakers and for needles, razors, gramophones, wireless, telephones and electrical instruments and apparatus of all kinds.

Another modern development is the increased resistance to mechanical stress of the alloy steel series, which has rendered possible the development of industrial processes requiring very high pressures, such as the hydrogenation of coal, in which the vessels used have to sustain pressures of three or four thousand pounds per square inch; and high-pressure steam boilers working up to 1,500 lb. per square inch at very high temperatures. These conditions introduce other difficulties, particularly the phenomenon known as 'creep', or the slow expansion of the metal under stress at high temperatures.

The development of alloy steels, both in their qualities of resistance to corrosion and high mechanical stress, has permitted the remarkable development of the aeroplane, the weight of the engines of which in the last few years has been reduced by nearly half for normal service. Radial engines had a weight of 2 lb. per brake horse-power fifteen years ago, and the latest for normal service are 1·2 lb. The first engines used during the War had a weight of 6·5 lb. per brake horse-power and those in normal use to-day are less than 1½ lb. The famous Schneider Trophy engines had a weight of only ¾ lb. per brake horse-power, and there seems little doubt that the normal aircraft engine in the near future will not weigh more than 1 lb. per brake horse-power for ordinary service, capable of 500 hours of operation without overhauling. In the case of the Schneider Trophy engines, it will be realised that they were designed as light as possible for a relatively short period of service.

The improvements in structural material, of which the tensile strength has been raised from the order of 30 tons to the order of 40–50 tons per square inch, have enabled the accomplishment of such engineering triumphs as the Sydney Bridge. This bridge, which spans Sydney Harbour, has an arch span of 1,650 ft. and five steel girder approaching spans on each side of the harbour, making the total length 3,770 ft. It has a total width of 159 ft. 6 in. and takes four lines of rail and six lines of vehicular traffic with two footways. It is 160 ft. above the water-line, and the highest point of the arch is 437 ft. above the high-water level. The arch itself rests on four main bearings. The two arches were built simultaneously from either side of the harbour, each springing from two main bearings and being supported by 128 cables in tension, and were built at such an elevation as to leave a gap of 40 in. to be closed in the centre. The closing of the gap was effected by a gradual loosening of the cables at the rate of about 2 in. a day. When the two half arches were finally brought into contact, they were in perfect alignment, a truly remarkable achievement.

The other great achievement of recent years is undoubtedly the Cunard White Star liner the *Queen Mary*, which, when launched, it was claimed, represented in its mass of 40,000 tons of steel the greatest mass ever moved by man unaided by mechanical power.

What of the future? As an engineer, I am presumptuous enough to think that metallurgy is even yet more of an art than a science. This view I believe is shared by many of our leading metallurgists. When, with the help of physical research, and the application of the ever-increasing means of physical investigation, we are able to ascertain more of the physical structure of the elements with which we are dealing, and thus perhaps predetermine some of the characteristics of the alloys of iron with other elements, we may well open up possibilities in the development of new materials, with such an improvement in mechanical properties as will render possible further developments in our use of mechanical power which may indeed transcend the limits of which we are at present capable. The influence of iron and its derivatives on our social organisation is therefore likely to continue to increase.

PRINTED IN GREAT BRITAIN BY FISHER, KNIGHT AND CO., LTD., ST. ALBANS

velocities were recorded for about ½ hour. The minimum of the preceding 11-year cycle having occurred at 1933·8, the present spot with respect to size is not unusual, but it is the largest one seen for more than a year, and its appearance is one of several indications that the new cycle is now well-established.

Announcements

DR. RICHARD ANSCHÜTZ, professor of chemistry in the University of Bonn, has been elected a foreign honorary fellow of the Royal Society of Edinburgh.

IT was announced at the general monthly meeting of members of the Royal Institution on July 1 that the Managers had elected Dr. Edward Mellanby to be Fullerian professor of physiology in the Institution, in succession to Sir Grafton Elliot Smith. The appointment is for a term of three years, in accordance with the provisions of the deed of trust of the professorship. Dr. Mellanby is the secretary of the Medical Research Council, and emeritus professor of pharmacology in the University of Sheffield. It is expected that he will give his first course of lectures at the Royal Institution in the autumn.

DR. R. F. LAWRENCE, who has been assistant in charge of reptiles, amphibians, and arachnids at the South African Museum since 1922, has been appointed director of the Natal Museum, Pietermaritzburg, as from July 1.

DR. HARVEY CUSHING, of New Haven, Conn., has been recently awarded the Gold Medal of the National Institute of Social Science in recognition of "distinguished services rendered to humanity". Dr. Cushing received the Lister Medal of the Royal College of Surgeons in 1930, and is the author of the life of Sir William Osler which won the Politzer prize for biography in 1925.

THE Hungarian Academy of Science has elected as honorary member Baron A. Koranyi, professor of internal medicine at Budapest.

THE annual conference of the Association for Combating and Preventing Corrosion, under the auspices of the Society of German Chemists (Verein deutscher Chemiker e.V., Berlin W 35, Potsdamer Str. 103a), will be held in Berlin on November 18–19, 1935. The subject for discussion is "Corrosion by Water".

THE President of the Republic of Peru has appointed a committee composed of the director of public health, the president of the National Academy of Medicine and Prof. Constantino Carvallo, as representatives of the medical faculty to elaborate a plan for the establishment of a serological institute which, in addition to producing serums and vaccines, will undertake researches in chemistry, bacteriology and biochemistry.

AN Electrodeposition Exhibition will be held in the Science Museum, South Kensington, from July 25 until October. The purpose of the exhibition is to illustrate all phases of electrodeposition and the underlying scientific principles. It has been organised by the Electrodepositors' Technical Society, Northampton Polytechnic Institute, London, E.C.1, from which further information can be obtained.

THE friends, colleagues and pupils of the late Prof. Léon Bernard, formerly president of the Health Section of the League of Nations and physician to the Hôpital Laennec, Paris, desire to honour his memory by placing a medallion of him in his hospital, and founding an international prize for social medicine. A reproduction of the medallion will be given to each subscriber. Subscriptions should be sent to the treasurer, M. Georges Masson, 120 Boulevard St. Germain, Paris, 6e.

A PARTY of Moscow men of science is about to explore the Kara Kum desert in Central Asia. The expedition will be absent for four months, and will investigate the natural resources of areas in the northern and south-eastern parts of the desert.

UNDER the title "Iodine for Livestock", a pamphlet has been issued free of charge by the Nitrate Corporation of Chile, Stone House, Bishopsgate, E.C.2. The pamphlet, which has been compiled by Mr. Frank Corrie, contains several excellent illustrations, and deals at length with the relation between iodine and the various problems of animal health and nutrition, and practical advice is given on the use of iodine in feeding stock.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

A lecturer in engineering in the Plymouth and Devonport Technical College—The Secretary for Education, Cobourg Street, Plymouth (July 10).

A lecturer in production engineering in the Dudley and Staffordshire Technical College—The Clerk to the Governors, Education Offices, St. James's Road, Dudley (July 10).

A lecturer and a student demonstrator in botany in University College, Exeter—The Registrar (July 12).

A chief Government mining engineer in the Department of Mines, Southern Rhodesia—The Official Secretary, Office of the High Commissioner for Southern Rhodesia, Crown House, Aldwych, London, W.C.2 (July 15).

An assistant professor of mathematics in the Royal Naval College, Greenwich—The Adviser on Education, Admiralty, Whitehall, S.W.1 (July 15).

An assistant demonstrator in physics in the Royal Holloway College, Englefield Green, Surrey—The Principal (July 17).

A lecturer in mathematics in the Bingley Training College—The Education Officer, County Hall, Wakefield, Yorkshire (July 24).

An assistant lecturer in civil engineering in Battersea Polytechnic, London, S.W.11—The Principal.

A lecturer in botany, zoology and microbiology in the College of Technology, Leeds—The Director of Education, Education Department, Calverley Street, Leeds, 1.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 33.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Adsorption of Aluminium Hydroxide by Kieselguhr

ALUMINIUM hydroxide is readily adsorbed by kieselguhr to form an adsorption complex which is remarkably stable. The hydroxide is deposited by the slow addition of a small excess of ammonia to a de-aerated suspension of 10 gm. of specially purified Superfloss kieselguhr in 100 c.c. of 2 per cent ammonium nitrate solution containing a known amount of aluminium nitrate, the suspension being vigorously stirred. The curve (Fig. 1) shows the relation between the ζ value of the preparations in $N/10$ acetic acid and the amount of aluminium hydroxide adsorbed by 100 gm. of kieselguhr.

This curve indicates that the surface of 100 gm. of kieselguhr is completely coated by 0·00486 gm.-mol. of aluminium hydroxide and that a maximum ζ value of +75·4 mv. is then obtained. Increasing the amount of aluminium hydroxide causes a decrease in the ζ value until a value of +61·2 mv. is reached, when 0·00972 gm.-mol. has been deposited. The deposition of further quantities of aluminium hydroxide does not change the ζ value of 61·2 mv., which is that of free unsupported aluminium hydroxide in $N/20$ acetic acid.

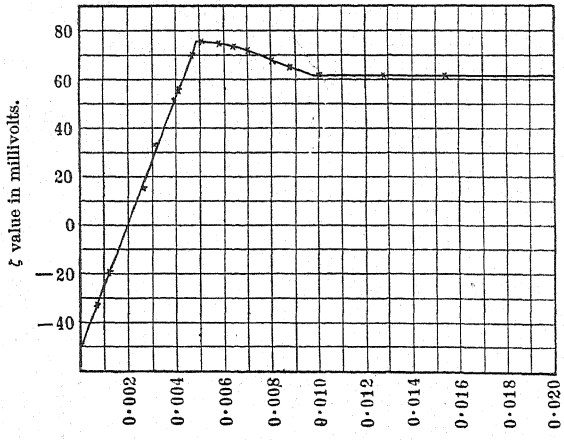

FIG. 1.

The total surface area of 100 gm. of the kieselguhr was determined by measuring the rate of sedimentation by the international pipette method, the assumption being made that the particles are spherical. By differentiation of the cumulative percentage curve, the values of $dW/d\log r$ were obtained and from these the values of $dS/d\log r$ were calculated. The area under the $dS/d\log r$, $\log r$ curve gave the total surface area as $1{\cdot}54 \times 10^6$ sq. cm. and it is manifest that this must be much less than the true surface area. If the true surface area be taken as five times that calculated, that is, $7{\cdot}7 \times 10^6$ sq. cm., then when 0·00486 gm.-mol. of aluminium hydroxide completely covers that area the diameter of each particle of the hydroxide on the surface is found to be $5{\cdot}77 \times 10^{-8}$ cm. Since this is of molecular dimensions, it follows that aluminium hydroxide is first adsorbed as a uni-molecular layer by the kieselguhr surface and that when this layer is completed the ζ value is +75·4 mv. It further follows that when a second uni-molecular layer of aluminium hydroxide has been deposited, the ζ value falls to +61·2 mv. and that this second layer has the same properties as the un-adsorbed substance.

Since the number of aluminium hydroxide molecules in the first and second layers must be the same, the enhanced ζ value indicates that the molecules in the adsorbed uni-molecular layer must be activated in some way. The observations, therefore, are analogous to those of de Boer and his colleagues[1].

In explanation of this activation, it may be suggested that an adsorption complex is formed of the type proved to exist in the case of solvates[2]. If the molecules in the surface be denoted by E and those of the adsorbed substance by S, the adsorption complex will be represented by E^-S^+, the molecule E having given one or more of its rotation-vibration quanta to the molecule S. Since this transference of energy cannot take place unless the two molecules have rotation-vibration frequencies in common, a surface must possess a selectivity in its absorptive power. It is interesting, therefore, to note that kieselguhr does not adsorb iron hydroxide ($Fe(OH)_3$) in spite of the similarity between the properties of $Fe(OH)_3$ and $Al(OH)_3$.

Spontaneous Super-Contraction of Animal Hair

SUPER-CONTRACTION induced in silk fibres by acid, and in wool by means of steam and chemical reagents, has been described by Farrell[1], Astbury and Woods[2] and Speakman[3] respectively. I have recently obtained evidence of super-contraction in the guard hairs of raw pelts taken from fur-bearing animals, the phenomenon probably arising through oxidation of

the disulphide link in keratin. As the furs had received neither heat nor chemical treatment, the condition described below apparently developed on the living animals. The fibres under consideration are distinguished by extra-normal curvature (Fig. 1*a*) which is generally greatest at the tip of the hair, and has been observed most frequently on the pelts of white and red foxes. The phenomenon may occur locally or be general to the whole skin, and when severe it gives a markedly frizzy appearance to the affected region.

Exposure of these fibres to steam increases the deformation in the same direction: a fox hair, the tip of which was deflected 180° before treatment, shrivelled to a close spiral of four or five turns, and contracted still further on drying (Fig. 1*b*). Immersion in strongly acid solutions reduces (in some cases reverses) the curvature, but subsequent washing and drying leads to an increase in the initial direction. Cold water reduces the curvature of the fibres whether or not they have been treated with chemical reagents or steam, but its action is reversed by drying. The curvature of these fibres before and after treatment can only be explained as due to a small difference in super-contraction of the keratin chains on opposite sides of the fibre.

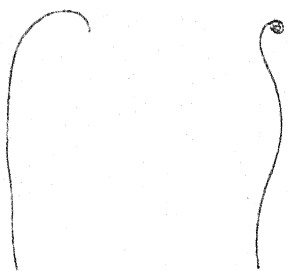

FIG. 1. White fox guard hair showing curvature due to super-contraction: (*a*) untreated; (*b*) steamed 10 minutes and dried. ×2½.

Disulphide and salt linkages between adjacent peptide chains appear to be prime factors opposing the contraction of keratin. When both are attacked, super-contraction occurs, as is evident from experiments carried out by Speakman[4]. There is no evidence that, in the absence of tension, either steam or acid has any rapid effect on disulphide linkages, but either is capable of disrupting the salt linkages[5]. Hence, in the abnormal fibres described, the contribution of the disulphide link to the lateral bonding of the molecules has been reduced sufficiently to permit super-contraction, which is greatly enhanced by opening the salt linkages.

The uncurling of fibres by acid, and the effect of cold water are obviously explicable in terms of swelling. The mechanism by which the disulphide link is attacked is probably oxidation via atmospheric oxygen in the presence of water and under the influence of light (ultra-violet?) This view is supported by Berger's observation[6] that sulphuric acid is produced in wool by exposure to sunlight. The production of curvature in normal fibres, by reagents that attack the disulphide link and permit super-contraction, is further evidence of the significance of this link in the phenomenon described. Such artificially damaged fibres behave, qualitatively, in the same way as abnormal specimens taken from the raw skin.

As some species appear to be free from the characteristic features described, it would be of considerable interest to know how widespread the abnormality is. I should be glad to hear details of cases in which it has been observed on living animals.

Nova Herculis and Cosmic Rays

SINCE the appearance of Nova Herculis in December last year, a number of notes have appeared in various scientific journals dealing with a possible effect of the nova on the intensity of cosmic rays, but the conclusions arrived at by different observers have been rather conflicting. It seems, therefore, desirable to examine as many observations as possible at different places and with different types of apparatus. The data obtained by means of a photographically recording Kolhörster electrometer of the latest type which was kept in continuous action at the Solar Physics Observatory, Cambridge, during the period from February 14 until March 20, appear to confirm Kolhörster's observations made with Geiger-Müller counters.

The instrument was installed inside a box-shaped shield of which the base was made of cast iron blocks of 6 inches total thickness and the walls and the top were made of 100-year old lead slabs of 4·5 inches total thickness. Between February 14 and March 4 the observations were made with the shield closed on all sides, while during the period March 4–March 20 the shield was open at the top. Hourly values of the cosmic ray intensity were determined from the photographic records and all the values were reduced to a common atmospheric pressure (about 29 in.), the pressures during the different hours being obtained from simultaneous barograph records. In order to find out if the nova was making any contribution to the cosmic rays the day was divided into four six-hourly intervals and the average values of the cosmic ray intensity were calculated for the different intervals. The results are given in the following tables:

CLOSED SHIELD (MEAN NOVA MAGNITUDE—3·3m)

Interval (G.M.T.)	Intensity in ion-pairs/cm.³/sec.	Remarks	
13h—19h	1·561	Nova highest	1·561
19h—1h	1·477		
1h—7h	1·546	Nova lowest	Average.. 1·492
7h—13h	1·452		

Increase = 4·5 per cent

OPEN SHIELD (MEAN NOVA MAGNITUDE—4·6m)

Interval (G.M.T.)	Intensity in ion-pairs/cm.³/sec.	Remarks	
14h—20h	2·506	Nova highest	2·506
20h—2h	2·449		
2h—8h	2·440	Nova lowest	Average.. 2·449
8h—14h	2·457		

Increase = 2·3 per cent

It will be seen that both for closed and open shields the intensity of cosmic radiation is highest during the 6-hour interval during which the nova is also at its highest altitude, but the intensity is lowest when the nova is at its lowest altitude only for the open shield observations. It is difficult to explain why for the 'closed shield' observations the intensity during the 'nova lowest' interval should be next in magnitude to that for the 'nova highest' interval. The observations have been taken at a time when the nova and the sun have been well separated in hour angle. That the observed effect is not due to a solar term can be seen from the following figures:

Closed Shield		Open Shield	
Interval	Intensity	Interval	Intensity
9h—15h	1·486	9h—15h	2·473
21h—3h	1·489	21h—3h	2·472

A detailed examination of the whole series of measurements is in hand, and the results will be published later.

Crystallisation of Seralbumins

IN NATURE of February 23, 1935 (vol. 135, p. 307), Dr. Muriel E. Adair and Dr. G. L. Taylor describe crystallised human seralbumin obtained by them.

It will interest readers of NATURE to learn that in the Biological Physical-Chemical Laboratory of which I had charge in the "Instituto Bactereológico" of the National Department of Hygiene (Director, Dr. A. Sordelli) a student of mine, Dr. Moisés Grinstein, made a systematic study of the crystallisation of seralbumin from different species of animals. His work was presented at a meeting on August 16, 1934, of "Las Sesiones Quimicas Argentinas" but the records have not yet been published.

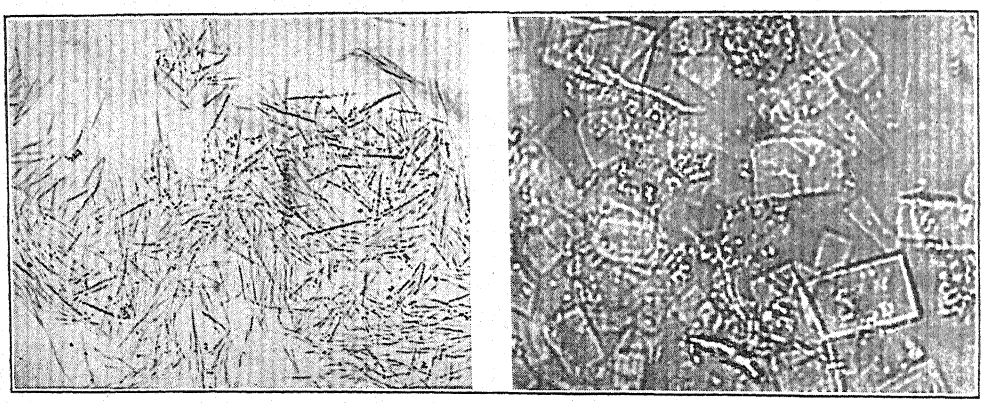
The technique used was that advised by Sorensen for crystallising horse seralbumin: the globulins are precipitated from the serum or plasma by semi-saturation with sulphate of ammonium. After filtering through paper a transparent liquid is obtained. This liquid is acidified by 0·5*N* sulphuric acid until a permanent turbidity is obtained, shaking continually; this happens when the reaction corresponds to a *p*H 4·6–4·8. After about twenty-four hours the precipitate is completely crystallised.

RAUL WERNICKE.

Buenos Aires.
April 19.

IN addition to the two photomicrographs here reproduced, Prof. Wernicke sent others of horse and mule albumins, but as the crystal form of horse albumin is well known, these photomicrographs are not reproduced. Dr. Adair and Dr. Taylor may be absolved from negligence in being unaware of Dr. Grinstein's work, as it has not yet been published. In the summary of their letter, which appeared in NATURE of February 23, p. 310, it should have been stated that the crystals obtained by them were from normal human sera and not from the sera of dropsical patients.

ED., "NATURE".



(*a*) (*b*)

FIG. 1. Crystal of (*a*) human seralbumin, (*b*) guinea pig seralbumin.

Dr. Grinstein tried to obtain crystals of seralbumin from men, horses, asses, mules, guinea pigs, rabbits, llamas, pigs, oxen, dogs and birds, and he obtained positive results with horses, asses, mules, guinea pigs and men.

I enclose photomicrographs of the crystals obtained (Fig. 1).

Occurrence of Unstable Choline Esters in Invertebrates

LOEWI, DALE, FELDBERG and their co-workers have emphasised the importance and physiological activity of acetylcholine in vertebrates[1]. The possibility of extending to invertebrates the cholinergic mechanisms described in mammals has, so far, not been tested experimentally. The first point investigated at Naples was the existence of unstable choline esters in tissue extracts of marine invertebrates.

Using Chang and Gaddum's technique[2], I have been able to find, in trichloracetic extracts of various tissues of *Octopus vulgaris*, a substance which possesses all the properties of unstable choline esters. Its action on the leech muscle, on the frog's rectus and the longitudinal muscle of *Holothuria stellata* is sensitised by eserine; its inhibitory action on the frog's heart and its vasodilator action in the eserinised cat is abolished by atropine. Like acetylcholine, the substance is destroyed in 10 minutes at room temperature by treatment with 2*N* caustic soda; it is also rapidly hydrolysed by an esterase present in the fresh blood of *Octopus*.

The activity of the same extract in different tests is about the same if expressed in acetylcholine

chloride. Hence it is believed that the substance present in extracts of invertebrate tissues is acetylcholine. The content in the organs of *Octopus* ranges from 0·1–0·2γ per gm. (skin, median ventricle) to 3γ per gm. (arms without skin) of wet tissue. The stomach and posterior salivary glands contain a fair amount (1·3γ per gm.). The blood and testicles have very little or none. The apparent acetylcholine content of *Sipunculus nudus* and of the longitudinal muscles of *Holothuria tubulosa* ranges from 0·9γ to 1·7γ per gm. Choline esterase is present in the blood, not only of *Octopus vulgaris*, but also of *Aplysia depilans* and *Murex*.

It thus seems that, in at least some invertebrates, the conditions for cholinergic nervous action are realised. This second point is now being investigated in *Octopus*.

[2] Chang, H. C., and Gaddum, J. H., *J. Physiol.*, **79**, 255; 1933.

P.S. The above letter had been sent to the Editor before I saw an advance proof of the communication by Mr. C. F. A. Pantin on the response of the leech to acetylcholine (NATURE, May 25, p. 875). *Hirudo* does not seem to be suited for detailed physiological analysis; *Octopus*, on the contrary, is a remarkable animal for experimental work. In addition to the facts already mentioned above, I wish to add the occurrence of a very large amount of acetylcholine (77γ per gm.) in the cerebral ganglia; this fact suggests that at the central synapses of this cephalopod a cholinergic mechanism is probably involved.

Dietary Hæmorrhagic Disease in Chicks

A NUTRITIONAL disease of chicks characterised by subcutaneous, intramuscular and abdominal hæmorrhages, prolonged blood-clotting time and erosions of the gizzard lining has been described in detail by Holst and Halbrook[1] of this laboratory. They were able to cure the disease by the use of fresh cabbage. The gizzard erosions and bleeding tendencies have been noted by McFarlane, Graham and Hall[2]. Dam and Schönheyder[3] have also produced the hæmorrhagic symptoms in chicks, and have shown that the disease is not caused by lack of any of the known vitamins. The same finding has been obtained by Halbrook[4].

Dam[5] has reported that the disease is caused by lack of an organic substance which was found present in hog-liver fat, hemp seed, tomatoes, kale and, to a less degree, in many cereals. The anti-hæmorrhagic factor was found to be present in the fat-soluble, unsaponifiable, non-sterol fraction.

Since the first publication from this laboratory[1], additional findings have been made. The disease can be prevented by so little as one half per cent of dehydrated alfalfa, and the anti-hæmorrhagic factor is located in the unsaponifiable, ether-extractable portion of alfalfa. Completely extracted alfalfa, chlorophyll and the saponifiable fraction of alfalfa ether extract fail to prevent the disease. The factor can be adsorbed from its ether solution by activated carbon. It is stable to heating at 120° C. for 24 hours.

The disease can be prevented by a concentrate prepared from alfalfa and fed at the level of 1/1,000 per cent of the basal diet. This basal diet consists of fish meal 20, dried brewer's yeast 12, polished rice 65, limestone 1, cod liver oil 1 and salt 1. Birds on the basal diet develop the disease to a severe extent, comparable with that described by Dam and Schönheyder[3].

In addition, the fish meal used in our basal diets can protect against the disease if allowed to remain in a wet condition for several days, thus affording opportunity for the action of micro-organisms. Rice bran treated in the same way will also afford complete protection, while the untreated rice bran fails to prevent the disease. A sample of the fish meal, completely extracted with ethyl-ether and kept in a moist condition for several days, will, after drying, yield a potent ether extract effective in small amounts when added to our basal diet containing the untreated fish meal.

For these reasons, anti-hæmorrhagic power cannot be attributed specifically to any feed ingredient unless the possibility of action upon it by micro-organisms has been guarded against. These results offer an explanation for the failure of Cribbett and Correll[6] to obtain symptoms of the disease on the Holst and Halbrook diet, and for the fact that samples of fish meals, meat scraps and commercial casein have often failed to produce the disease.

In an experiment to determine a possible causative factor in fish meal, the fish meal was diluted with varying amounts of a mixture of purified casein and bone ash compounded so as to resemble the fish meal. The sample of fish meal used in this case was a different lot from that formerly used although obtained from the same manufacturer. When this fish meal alone was used as the animal protein, the symptoms were only moderately severe. However, the severity and early onset of the disease markedly increased as the proportion of purified casein replacing the fish meal increased. The severity of the disease was also noticeably greater on lower levels of dried brewer's yeast. The results indicated the presence of small but inadequate amounts of the anti-hæmorrhagic factor in both of these samples of fish meal and yeast, rather than a specific disease-promoting factor in the fish meal.

Replacement of 50 parts of polished rice by wheat or yellow corn fails to prevent the disease. The results indicate very little, if any, of the anti-hæmorrhagic factor in these cereals.

In regard to the chemical and physical properties of the anti-hæmorrhagic factor, our work closely agrees with that of Dam[5]. The nature of this substance is being actively investigated.

An Insulin Inhibiting Agency in the Duodenum

HELLER[1] and Labarre[2] have reported that some of their preparations of the insuletropic hormone failed to demonstrate the usual increase in sugar tolerance in animals, and are unable to ascribe this to any definite cause. Others also report inconsistent results. Since 1929, using a method reported in conjunction with N. B. Laughton[3], I have noted that it is extremely critical, and deviation at one stage yields negative results.

The inertness of the preparations could not be ascribed solely to mere deficiency in the hormone content, since, while such preparations did not affect the blood sugar values of normal rabbits, these animals displayed a distinctly lowered sugar tolerance. Also such preparations were hyperglycæmic in their action on diabetic patients.

Striking effects were obtained where 'inactive' preparations were investigated on the insulinised rabbit. Controls were given 1 rabbit unit of insulin per 2 kgm. weight and the blood sugar values observed for 6–8 hours. These invariably gave the usual response—the sugar values dropping to 50 mgm. within 2 hours and remaining at this level for 3–4 hours longer. Afterwards, these same animals were treated with the defective preparations and then this standard amount of insulin administered. In some cases no fall in the blood sugar was observed, while in average cases the blood sugar values did not fall below 70 mgm. in 2 hours, and returned rapidly to 100 mgm., usually reaching 130–150 mgm. 4 hours after administration of insulin.

The failure to observe the customary effects of the insuletropic hormone was due to the preponderance of this insulin antagonistic element. After this had been separated, the preparations became insuletropically active, although extreme activity could be developed by further treatment.

The effect of the insulin inhibiting principle, like that of the insular hormone, persists for some weeks after its discontinuance, and a study of this factor in cases of hyperinsulinism is in progress.

The methods by which the above results were obtained will form the basis of a subsequent publication.

Experimental Deafness

CONTINUED investigation similar to that described elsewhere[1] has provided evidence for the view that the phenomenon designated 'auditory fatigue' by Ewing and Littler[2] and Rawdon-Smith[1] is in reality the result of the intervention of certain cortical factors. The marked decrease in sensitivity of the human ear following upon stimulation by loud pure tones for several minutes is, it has been found, not confined to the ear stimulated. The nominally unstimulated ear suffers a loss of sensitivity sometimes as great as that in the stimulated ear. Further, the loss of sensitivity in either may be temporarily removed or lessened in many cases by subjecting the observer to an unexpected stimulus (such as momentary darkness). This will be clear from Fig. 1.

It would seem, therefore, that the phenomenon of so-called auditory fatigue may more correctly be termed *inhibition*. The result of an unexpected stimulus is to produce momentary disinhibition.

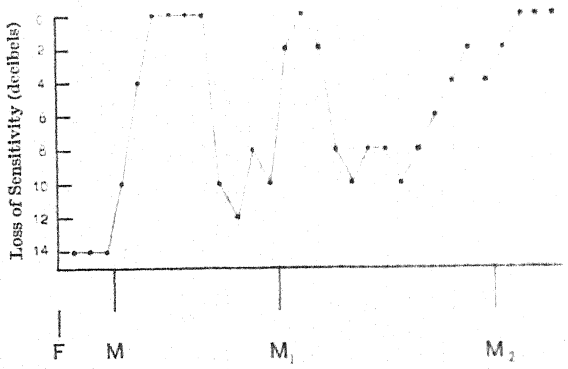

FIG. 1. Chart from actual record obtained from male subject. Each point represents one threshold reading. The points have been joined merely for convenience of interpretation—there is no indication that the threshold would fall on the line between readings. Frequency of stimulating and test tones = 2000 cycles per second. The stimulating tone ceased at *F*; *M*, M_1, M_2, represent points of application of momentary darkness in the sound-proof room in which the tests were made.

These effects find their nearest parallel in the phenomena of inhibition and disinhibition (or inhibition of inhibition) of conditioned reflexes described by Pavlov[3].

It is hoped shortly to publish these results in greater detail.

The Band Spectrum of NH

IN the course of our investigation of the spectrum of discharges through streaming ammonia, it has been possible to record the λ 2530 band of NH, described by Hori[1], with a Hilger E.1 quartz spectrograph, using an improved type of hollow cathode. In addition, we have obtained four weaker bands at λλ 2730, 2835, 2885 and 2980 which appear to be due to the ion NH^+.

Our analysis with higher dispersion shows the necessity for revising Hori's interpretation of the λ 2530 band. The initial level is found to be $^1\Sigma^+$, while the final level is identified with the $^1\Pi$ level common to the λ 3240 band ($0,0\,^1\Pi \rightarrow {}^1\Delta$) and the λ 4502 band[2] ($0,0\,^1\Pi \rightarrow {}^1\Sigma^+$).

Full details will be published shortly.

The Classification of Coals

I HESITATED to answer the letter published in NATURE of June 1 from Prof. Bone because so long ago as the year 1918 he indicated to me with emphasis that he did not desire any co-operation between chemical and palæobotanical work on coal.

May I, however, point out that he incorrectly says that the terms vitrain, clarain and durain are "imported from France". They are words coined *de novo* by myself in my paper in the *Philosophical Transactions of the Royal Society* in 1919. They do not correspond to the popular 'bright' and 'dull' coal, but were originally diagnosed for ingredients recognised as containing materials with distinct physical properties, and different types of cokes.

That Prof. Bone does not adopt my nomenclature or care to see the differences perceivable to others is a matter for his own orientation about which argument is unsuitable. But he is surely ill-informed to imply that "outside the exclusive circle of the 'Coal Research Club' " these ingredients do not receive recognition. A complete bibliography of coal research since 1919 would show how widely they are adopted. He is briefly answered by the words of M. Duparque (secretary of the Geological Society du Nord), *not* a member of the Coal Research Club, who, writing in 1924 of the laminations in coal, cited the important works of Bertrand, Renault, Grand 'Eury, Wheeler, Seyler, Potonie, Zalessky and others and said: "De tous ces travaux, ceux de Madame Marie Stopes ont eu la plus grande influence sur la direction de toutes les recherches concernant la houille".

Stationary Optical Paths

REFERRING to Dr. Karl Darrow's[1] article on quantum mechanics, Mr. T. Smith[2] has pointed out that optical paths are not (as Darrow repeats in his article) paths sometimes of maximum and sometimes of minimum time; but that the time is a minimum if the path does not include an image of an end point, and if the path includes an image then the time is neither a minimum nor a maximum. Smith has further elucidated this point in connexion with Darbyshire's[3] recent letter.

The close analogy so significant on wave mechanics between the principle of least action in classical mechanics and the principle of stationary time for optical paths (Fermat's principle) is well known. The principle of least action[4] states that the action is a true minimum, provided that in passing along the trajectory of the particle the final point is reached before the kinetic focus of the initial point. But when the kinetic focus of the initial point is reached before we arrive at the final point, the action is neither a maximum nor a minimum. The definition of the kinetic focus is akin to the definition of image given by Smith in his recent note. Thus we see that the relationship between Fermat's principle and that of least action is not fully exhibited unless we take into account for optical paths the facts emphasised by Smith and so often ignored in text-books on optics.

Points from Foregoing Letters

FROM the amount of aluminium hydroxide adsorbed by kieselguhr (diatomaceous earth) and from the resulting electrokinetic potential (ζ) of the particles, as shown by their movement in an electric field, Prof. E. C. C. Baly and Mr. W. P. Pepper conclude that aluminium hydroxide is first adsorbed as a unimolecular layer giving a ζ-value of 75·4 millivolts. This layer is then able to adsorb a second molecular layer, resulting in a drop in the value of ζ to 61·2 mv.

Super-contraction of animal fibres has been induced artificially by various means. Dr. R. O. Hall describes a naturally occurring example of the phenomenon and proposes a tentative explanation in terms of the disulphide linkage of keratin.

Dr. A. K. Das gives results obtained by means of a continuously recording electrometer which was in action at Cambridge from February 14 until March 20. These photographic records appear to confirm Kolhörster's observations, made with Geiger-Müller counters, indicating an increase in the intensity of cosmic rays during the hours when the star Nova Herculis was at its greatest altitude.

Following upon the recently-published note in NATURE by Dr. Adair and Mr. Taylor, who had succeeded in obtaining seralbumin from normal human sera, Prof. Raul Wernicke now submits photomicrographs of crystals of human and guinea pig seralbumin obtained last year by Dr. Moisés Grinstein of Buenos Aires, and describes the method used in obtaining the crystalline preparations.

Having succeeded in extracting from various organs of the *Octopus* and other invertebrate marine animals a substance giving the physiological reaction of unstable choline esters, Dr. Z. M. Bacq infers, as C. F. A. Pantin did recently, that the rôle of acetylcholine in the nervous mechanism of invertebrates is similar to that in the higher animals.

Mr. H. Dam recently indicated the existence in hog liver fat, tomatoes, etc., of a new vitamin, K, which prevents a deficiency disease in chicken, leading to bleeding tendencies and other symptoms. H. J. Almquist and E. L. R. Stokstad point out that the new vitamin is also present in dehydrated alfalfa and in fish meal or rice bran that have been kept in a wet condition.

Prof. A. Bruce Macallum describes experiments indicating that certain extracts from the duodenum contain, in addition to the hormone which stimulates the secretion of insulin, a further component which is antagonistic to insulin.

The effect of unexpected stimuli in reducing or eliminating experimental deafness produced by loud 'pure' noises, and the fact that such deafness extends to the other ear even when it is not directly exposed to the noise, leads Mr. A. F. Rawdon-Smith to attribute the so-called auditory fatigue to an inhibition effect in the brain cortex rather than to a local effect in the ear.

Research Items

Roman Fort at Brough

THE existence of a Roman fort at Brough, Yorks, where Ermine Street crosses the Humber, as distinct from a riverside settlement, has been determined only recently. In 1933 an investigation was made of the character of the Roman occupation, previously well attested by frequent finds of coins, sherds, etc., by trial trenches dug in the Bozzes Field by Mr. T. Sheppard, Dr. J. L. Kirk and Mr. Philip Corder. In an interim report by the last-named (Hull Museum Publications, No. 182) a number of facts were established, notwithstanding that at the time of writing the excavation was not complete. A military station involving at least two, and probably three, ditches was established at Brough before the campaigns of Cerialis and Agricola. On the south side, the two outer ditches had been levelled and succeeded by an occupation area represented by floors, hearths and a rubbish pit. In the rubbish pit were Roman sherds, imitating Belgic forms, dated from material from Colchester at somewhere between A.D. 56 and 76. From these the inference is drawn that the occupation antedates the campaign of Cerialis, who founded Malton and York in the seventies. The earliest rampart on the east side was of compact sand and has not yet been positively dated. It is probably contemporary with the ditches on the east and south sides of the fort. Eventually the rampart was cut back and a solid stone revetment added. This was probably in the second century. Sherds from the filling of the ditches are none of them later than the Antonines. Probably the ditches were filled in the second century, when the military occupation was moved to the northern frontier. Third and fourth century occupation is attested by coins and pottery, and a large rectangular building in Trench 1 must fall within these centuries. It is not aligned with the ditches and may have been built after they had ceased to exist. Pottery of the fourth century was found unstratified in considerable quantity.

Bay Islands' Culture, Honduras

'LAS ISLAS DE LA BAHIA', a little-known group of islands off the northern coast of Spanish Honduras, have been investigated by expeditions of the American Museum of Natural History (1931) and the Smithsonian Institution (1933), and archæological collections were made in 1930 and 1931 by Mr. Mitchell-Hedges on behalf of the Museum of the American Indian, Heye Foundation. In a study of the archæology of the islands by Dr. W. D. Strong (*Smithsonian Misc. Collect.*, 92, 14) the observations of the two expeditions are combined and the material collected by Mr. Mitchell-Hedges is used for purposes of comparison. The majority of the known archæological sites are on hill-tops, next come caves and rock-shelters; springs and water-holes and large level sites are less frequent. The majority of the sites are shrines, or places of offering of some sort; habitation sites are rare, only four being known, of which one is doubtful, though showing the only known example of, possibly, the foundation walls of a house. Low earth mounds contain scattered burials. The pottery is classified as Monochrome, Elaborate Monochrome, Polychrome i and Polychrome ii, a chronological sequence in which Elaborate Monochrome and Polychrome i seem to be contemporary. The Bay Islands' culture lies on the northern fringe of an important, but little-known, cultural region. It appears to have certain affinities with Maya culture, but this is late and indirect, whereas the affiliation with the western Nicaraguan and northern Costa Rican culture is both intimate and direct. Southern traits permeate the whole culture, and seem to be early and basic. Historical evidence, ethnology, archæology, and linguistics, all combine to suggest that peoples of South American affiliations must have been responsible for most of the remains on Bay Islands and probably for those of northern Honduras as well.

Factorial Analysis of Human Abilities

IN the *Human Factor* (9, No. 5) Prof. Godfrey H. Thomson states briefly, and in as non-mathematical a way as possible, his criticism of Prof. Spearman's 'Two-Factor Theory'. He regards g as a mathematical variable without any real existence as a separate entity; and argues that the g arrived at by one set of tests is not necessarily the same as that arrived at by another set of tests. He refers to the American work on factorial analysis, which has been concerned with applying the method to any team of tests, and not only hierarchical teams of tests, and points out that an infinite number of mathematically satisfactory results are possible. Prof. Thomson gives illustrations to show the innumerable interpretations that could be made from any one set of correlation coefficients. Determining which of them should be selected is the business of the psychologist, not the statistician. His own belief is that the mind cannot be divided up into unitary factors, but is "a rich comparatively undifferentiated complex of innumerable influences".

Musculature of the Blue Crab

MISS DORIS M. COGHRAN has studied the musculature of the blue crab, *Callinectes sapidus*, Rathbun (Smithsonian Miscellaneous Collections, vol. 92, No. 9 (Publication 3282), Jan. 1935). This is an excellent piece of work and one much wanted, for few accurate observations have been made on such an important subject. The chief myological publications in existence relate to crayfish, shrimps and prawns. The complete fusion of the segments of head and body in the crab has resulted in the disappearance of those intersegmental muscles which, in crustaceans like the shrimp and crayfish, give a high degree of flexibility to the movements of the body. On the other hand, the muscles of the appendages are highly complicated, as are also those of the stomach with its gastric mill and of the alimentary system. The abdomen of the blue crab, in the male at least, is apparently progressing towards a condition of partial rigidity, as the third, fourth and fifth segments are immovably fixed in that sex. This fusion is not yet completely established, as the former segmentation is still partly

maintained in its musculature. The female's abdomen has six distinct segments, all of which have the muscles well developed. All these muscles are described in great detail, and there is a discussion of the general structure of the crustacean appendage. The numerous illustrations in the text add much to the value of this undoubtedly valuable work.

Marine Fauna of the Dutch East Indies

NEW parts of Résultats Scientifiques du Voyage aux Indes Orientales Néerlandaises de LL. AA. RR. le Prince et la Princesse Léopold de Belgique (*Mém. Roy. d'Hist. Nat. de Belgique*, Hors série, Vol. 11) recently published embrace Opisthobranches and Silicodermes (Onciades) by A. Labbé; Prosobranches Parasites by W. Adam (fasc. 14); Sponges by H. V. Bröndstad (fasc. 15) and Cephalopoda by W. Adam (fasc. 16). A. Labbé has discovered that the Oncidiidæ possess a siliceous armature, hitherto unknown, and that the different members of the family have in their bodies more or less widely distributed spicules of silica. For this reason he has proposed the sub-order Silicodermatæ, being synonymous with the Oncidiidæ of Gray. Not only has he made this innovation, but he has also placed them among the Opisthobranchs rather than the true Pulmonates, for he is of the opinion that the Silicoderms play the same rôle with regard to the Opisthobranchs as the Pulmonates do with regard to the Prosobranchs. Seven species were taken by the expedition, five *Oncidium*, three new, two already known, one not determined owing to bad preservation, and one *Oncidiella*. No mention is made of the very careful monograph on South African Onchidella by Hugh Watson (*Ann. South African Mus.*, 20, 1925) which contains valuable anatomical work and discussions on the geographical distribution. The capulid *Thysa crystallina*, parasitic on the echinoderm *Linckia*, is described by W. Adam, who has discovered the minute male, hitherto unknown, under the shell of the female. The male is mature although less than a millimetre in length and has no disc of fixation. The author, agreeing with Jonker, determines that this disc, which has been subject to much discussion, is part of the head, being innervated exclusively by the cerebral ganglia.

Pacific Entomological Survey

Two publications (Nos. 6 and 7) of the Pacific Entomological Survey have been issued as Bulletins 113 and 114 of the Bernice P. Bishop Museum, Honolulu, 1935. Bulletin 113 is concerned with reports of various specialists on the insects and other arthropods collected in the Society Islands. Bulletin 114 comprises the second instalment of reports on the insects, arachnids, etc., obtained in the Marquesas Islands. These two bulletins are well illustrated and contain descriptions of numerous species hitherto unknown. The bulletins are of interest to students of geographical distribution and of island life in particular, as well as to specialists in the diverse groups concerned.

Physiological Differences between Geographical Races in Forest Mice

INVESTIGATION of the effect of mountain climate upon the human organism has shown that the ascent of high mountains causes an increase in the hæmoglobin content and in the number of erythrocytes in the blood. It is known also that these values are higher in the blood of some mountain animals, as well as of men living normally at high altitudes. The nature of these differences, however, have remained unknown; they may represent either a temporary individual adaptation (as in the case of a man ascending a mountain peak), or they may become fixed during individual or phylogenetic development. Some light on this interesting problem has now been thrown by Kalabuchov (*C. R. Acad. Sci.*, Leningrad, 2, No. 1, 1935) who has made a comparative experimental study of two sub-species of the forest mouse, *Apodemus sylvaticus ciscaucasicus* living at high altitudes, and *A. s. mosquensis* from the plains. Careful counts of the number of erythrocytes proved that the number was constantly higher in the mountain race than in that from the plains. When mice of the mountain race were transferred to the plain, the number of erythrocytes in their blood at first decreased, but two months later the number became normal, and even rose somewhat above the normal. In the controls, consisting of an equal number of plains mice race kept with the experimental animals, no change in the erythrocyte number was observed. This shows that there is a constant physiological difference between two races, independent of the environment.

A Fertile Species-Hybrid

GENETICISTS usually find that when two species are crossed, the offspring, if any, are sterile. Several garden plants have, however, originated as hybrids between two well-defined species, and now another plant has been found to have a similar origin. It is the pink-flowered chestnut, *Aesculus* × *Carnea*, recently described by Mr. M. B. Crane (*J. Roy. Hort. Soc.*, April 1935). Several well-authenticated instances of successful propagation of the hybrid from seed have been described in the garden literature of last century. Mr. Crane shows that each of the parents has twenty chromosomes, and upholds Skovsted's demonstration that *Aesculus Hippocastanum* has twenty small chromosomes in the germ cells, whilst *A. Pavia* has a similar number of large ones. The hybrid has forty, half of which are large, and the others small. Doubling seems to have been effected by autosyndesis—the non-reduction of both parental germ nuclei—since no parental types appear in the offspring. Several other species-hybrids are mentioned in the paper.

Effect of Rootstocks on the Nutrition of Apple Trees

MR. L. G. G. WARNE, of the University of Bristol, and Dr. T. Wallace, of Long Ashton Research Station, have investigated "The Composition of the Terminal Shoots and Fruits of Two Varieties of Apple in Relation to Rootstock Effects" (*J. Pomol. and Hort. Sci.*, 13, No. 1, pp. 1–31, March 1935). Several metabolic disturbances, such as leaf-scorch, have been observed in association with the use of certain types of rootstocks, and the paper under review shows that the various clones of stocks classified by Hatton at East Malling Research Station have certain well-marked effects upon the metabolism of the scion with which they are grafted. Malling stocks types II and V, known to be susceptible to potash deficiency, showed evidence of potash starvation even when that element was present in the soil in abundance. Rootstocks promoting great vigour in the scion produced a high ratio of potash to nitrogen

in the shoots, whilst a positive correlation was established between the ratio of phosphate to nitrogen in the wood, and precocity of bearing of the tree. The dwarfing effect of type IX could not be explained chemically. Many other results are set out in detail in the paper, and the chemical analyses have been correlated with extensive pomological records collected by Dr. T. Swarbrick and his colleagues.

Atmospheric Visibility

A DISCUSSION of the principles underlying the choice of the marks used in the estimation of atmospheric visibility, by W. E. Knowles Middleton, of the Meteorological Service of Canada (*Monthly Weather Review*, January 1935, p. 17), summarises very briefly the results of recent work in Germany and America on the measurement of the transparency of the atmosphere. This is a subject that has become more important in the last twenty years on account of the development of aviation, and is one which abounds in practical difficulties. It has long been known that the distance expressing the so-called 'visibility' of the atmosphere when determined by observation of the distance of the farthest of a selected group of objects such as trees, buildings, etc., is influenced by a number of factors unconnected with the state of the atmosphere, for example, by the excellence or otherwise of the observer's eyesight, and perhaps still more by the nature of the selected objects and the background against which they are seen. Mr. Knowles Middleton states that it is a common opinion that observations of this element made by the method just described are of no use in synoptic meteorology. He goes on to show that it is only when the objects used are black or nearly black and are seen against the sky that we are in effect measuring σ, the extinction coefficient of the atmosphere, defined by the equation $dE = -\sigma E dx$, where E is the flux density in a parallel beam of light travelling in the direction of x. His remedy is to use only black or nearly black objects against the horizon sky during the daytime, and never objects against terrestrial backgrounds, and to use interpolated values obtained from observations of such objects rather than misleading observations derived from an inspection of objects which appear against terrestrial backgrounds; and to have night observations made with the aid of some standard transmission meter, so that these may be independent of the local distribution of lights not set up specially for observations of visibility.

Solidification of Nitrogen and Argon

THE *Proceedings of the American Academy of Arts and Sciences* of March contains Prof. P. W. Bridgman's account of his determinations of the melting points of nitrogen and argon under pressures up to 6,000 atmospheres, their change of volume on, and latent heat of, fusion. The gas was contained in a chromium-nickel-steel cylinder closed by a gas-tight piston the movement of which gave the change of volume. The cylinder was surrounded by a liquid propane thermostat, the temperature of which was regulated by a hydrogen thermometer. The temperature of the gas was measured by a copper-constantan thermo-couple and its pressure by a manganin wire resistance gauge. The melting point of nitrogen rises from 63·3° K. at 1 atm. to 149° K. at 6,000 atm., the increase of volume on melting changes from 0·072 to 0·026 c.c. and the latent heat of melting from 218 to 346 kgm.-cm. per gram. For argon the figures are 83·9° K. to 193° K., 0·080 to 0·021 c.c. and 280 to 288 kgm.-cm. per gram. In each case, the change of melting point is nearly a linear function, and the increase of volume a hyperbolic function, of the pressure. The latent heat of fusion is in both cases nearly constant at pressures above 3,000 atmospheres.

Diffusion of Gases through Metals

C. J. SMITHELLS and C. E. Ransley (*Proc. Roy. Soc.*, A, May) have examined the diffusion of several gases through different metals, and thus obtained a more definite conception of the mechanism involved. The metal tubes were heated electrically and provision was made for analysing the gas which had passed through the tube walls. The dependence of the diffusion on pressure and temperature was investigated. The effect of temperature was satisfactorily represented by Richardson's exponential expression. Except at low pressure, the variation with pressure follows a $\sqrt{P}$ law, the diffusion probably taking place in the atomic state. According to the view of the authors, diffusion is always preceded by adsorption, and the deviation from the square root law may be explained by the use of the Langmuir isotherm. The diffusion is found to be strongly specific; nitrogen, for example, will diffuse freely through iron, chromium, or molybdenum, but not through copper, while no diffusion of argon or helium could be detected with any metal. This agrees with the view that activated adsorption is necessary for the diffusion.

Chemical Aspects of Biological Oxidation

IN his presidential address at the annual meeting of the Indian Chemical Society on January 4, Prof. N. R. Dhar discussed the chemical aspects of biological oxidations (*J. Indian Chem. Soc.*, 12, 96; 1935). Researches carried out in his laboratory have shown that organic substances, which are not directly oxidised by atmospheric oxygen at the ordinary temperature, can be oxidised by simply passing air through their solutions or suspensions when they are mixed with compounds which readily undergo oxidation in air, such as sodium sulphite, phosphorus, or freshly precipitated ferrous, cerous and manganous hydroxides. It has been found that proteins are more readily oxidised than carbohydrates, and carbohydrates than fats; in fact, the order is the same as was found by Voit in feeding experiments; with cerous hydroxide, as much as 83 per cent of egg white is oxidised, 57 per cent of starch and 30 per cent of butter. In all cases, the substance is oxidised completely to carbon dioxide and water. Prof. Dhar contrasted this process with the rapid oxidation of foodstuffs with hydrogen peroxide or a ferrous or ferric salt, in which intermediate compounds are formed, and compared the former with normal metabolic oxidations and the latter with the changes occurring in abnormal metabolism, such as the appearance of the 'acetone' bodies in diabetes or fasting, from the incomplete combustion of fats. In conclusion, he suggested that certain biologically active compounds, which are reducing agents, owe their activity to their power of inducing oxidations in other substances, and also directed attention to the effect of sunlight in inducing oxidations in the presence of air.

The National Physical Laboratory, Teddington

INSPECTION BY THE GENERAL BOARD

ON June 25, the General Board of the National Physical Laboratory made its annual inspection of the Laboratory. A large number of visitors were present, including members of scientific and technical institutions, Government departments and industrial organisations, and were received by Sir Frederick Gowland Hopkins, president of the Royal Society and chairman of the Board, the Right Hon. Lord Rayleigh, chairman of the Executive Committee, and the director of the Laboratory, Sir Joseph E. Petavel.

In the Physics Department of the Laboratory a number of problems connected with air conditioning of public buildings are being studied. Mention may be made of an examination of the water vapour absorptive properties of various classes of books, and of an investigation of the relationship between humidity and length for a number of hygroscopic substances, to ascertain their suitability for use in humidity-controlling apparatus. In the course of an investigation of the action of the wet and dry bulb hygrometer at low temperatures, a dew point apparatus has been developed for use as a standard of reference. In this, paraffin oil cooled by solid carbon dioxide circulates in a spiral path, attached to the back of a disc of chromium-plated silver, the temperature of which is measured by means of a thermo-element.

The apparatus devised for the determination of the ratio of the specific heats of carbon monoxide has been modified so that measurements of the velocity of sound can be made quickly at any one of several widely spaced frequencies. Electrically maintained quartz crystals are carried on a plate capable of rotation beneath the opening of a vertical furnace containing the gas under test. Each crystal gives a definite frequency so that the change of velocity with frequency can be determined at various temperatures of the gas.

For the measurement of the thermal conductivities of refractory materials, a test slab eighteen inches square and two inches thick is used. One face can be heated to 1,100° C., and the heat transmitted through the central area is determined by means of a water-flow calorimeter.

In the Radiology Division the relation between crystalline structure and the magnetic, electrical and tensile properties of materials is under investigation by X-ray diffraction methods, special attention being given to the detection and measurement of internal strain. This strain results in a broadening of the diffraction lines, and the degree of broadening can be used as a measure of the amount of strain present. New equipment has been added to the Division for the study of materials by electron diffraction methods.

The measurement of gamma-ray dosage in röntgens is under investigation and experiments have been made with both 'free-air' and 'air-wall' chambers, the latter having walls composed of materials of effectively the same atomic number as air. The effect of wall thickness on the ionisation produced in 'air-wall' chambers is being examined. A thick-walled chamber appears to indicate the dosage under conditions prevailing in deep-seated therapy, while a thin-walled chamber measures virtually the dose received at the surface.

In the Acoustics Laboratory considerable attention is being given to the problems of noise abatement and measurement. Investigations are being carried out on the sound-insulating properties against impact and air-borne noise of walls and floors of various designs. The use of absorbent materials in this connexion is being studied. For the measurement of noise, a portable acoustimeter has been developed in the Department. The instrument gives equal indications for notes of the same loudness, irrespective of pitch.

In the Optics Division a new type of colorimeter containing no rotating elements has been constructed. The light enters the mixing chamber through a condensing lens equipped with variable apertures containing the primary colour filters. Colour mixing is effected by the use of a small integrating sphere as a mixing chamber, the intensity of each primary stimulus being controlled by variation of the apertures.

In the Electric Standards Division of the Electricity Department consideration has been given to the construction of standard attenuators of calculable phase angle for the calibration of commercial attenuators at radio frequencies up to 1 mega-cycle per second. A combination of two of the laboratory residual inductance standards in the form of a potential divider can be used as an attenuator, and a number of units of this type have been constructed ranging in value from 1 decibel to 110 decibels.

An apparatus for the automatic comparison of frequencies by counting beats has been developed in the Division. The apparatus makes use of a system of relays which actuate, on one hand, a counter registering the number of beats produced by the two frequencies being compared, and, on the other hand, a counter registering seconds or fractions of a second down to one tenth of a second.

In the High Voltage Laboratory, oscillographic methods have been applied to the testing of lightning arresters. Experimental arrangements have been developed for determining the volt-ampere characteristics of arresters, the lag in their response to steep fronted overvoltages and their ability to interrupt the flow of current when the overvoltage has been disposed of. Records were shown illustrating the voltage acquired by a piece of apparatus with and without the arrester connected across it.

Research work is being carried out in the Electrotechnics Division of the Department on the alternating-current resistance of conductors for heavy currents. Formulæ have been developed for solid circular conductors giving close agreement with experimentally measured values. The problem of tubular conductors is now under examination.

An investigation is in progress in the Photometry Division to determine the illumination at which it becomes necessary to supplement daylight by

artificial light, and automatic means have been developed for recording this in the case of a number of selected office lights. A solenoid included in each office lighting circuit operates the shutter of a cine-camera when the light is switched on. Each exposure records the date, the time of day, which office light is switched on, and the reading of a calibrated ammeter and rectifier photo-cell unit. This reading determines the illumination in the office. In the same Division research is being undertaken to determine the change of sensitivity of the eye during recovery from exposure to high brightness backgrounds or to isolated bright sources of light. The work has applications to the problem of the recovery of eye sensitivity from the glare of motor-car headlights.

In the Radio Department an exhaustive examination of the factors responsible for departure from frequency stability has revealed the necessity for high thermal and secular stability on the part of the inductance and capacitance. An inductance coil and variable condenser possessing extremely low temperature coefficients were exhibited; in these, use is made of differential expansion systems.

Attention has been given to the use of inverted diodes, split-anode triodes and magnetron oscillators as generators of very high-frequency oscillations. A demonstration was given of the generation, by a four segment magnetron, of ultra-short waves in a Lecher-wire system connected to the segments of the anode.

In the course of research on direction finding, a potentiometer method has been developed for the excitation of a rotating radio-beacon. The method utilises a dual potentiometer connecting an oscillator to two amplifiers which feed two pairs of aerials arranged at right-angles. The motion of the potentiometer contacts is such that the voltages applied to the two amplifiers vary sinusoidally and in opposite phases, producing a rotating field in the aerial system.

In an investigation into the nature and origin of atmospherics, oscillographic records have enabled the wave form and direction of individual atmospherics to be determined. Simultaneous records obtained at two different stations permit the place of origin of the atmospheric to be ascertained. Results obtained have shown that the recorded wave form of an atmospheric depends on the distance of the source producing the disturbance.

In the Metrology Department the standard leading screw lathe used for the correction of the pitches of lead screws has been entirely reconstructed. The traverse has now been extended to five feet and, by the introduction of change gears, screws having any English or metric right-handed pitches can be dealt with. Calibration of the reconstructed lathe has shown that its cumulative pitch is correct to within 0·0003 inch throughout its traverse.

New apparatus has been constructed for the direct testing of mercurial barometers at pressures varying from 2 in. to 34 in. of mercury, the pressure being accurately controlled by a specially designed barostat. The apparatus can accommodate five barometers for test in addition to the standard mercury barometer. A standard barometer has been constructed combining the principles of the Fortin, Newman and Kew barometers, so that instruments of all three types can be tested directly in the new apparatus.

The study of fatigue in relation to crystal structure has been continued in the Engineering Department and the effect of crystal orientation on fatigue strength is being examined for a number of single crystals of aluminium. Attention is also being given to the effect of intercrystalline boundaries on fatigue failure and tests are being made on specimens consisting of several crystals of aluminium. Specimens and results illustrating these two phases of the work were exhibited. For the determination of the fatigue strength of materials under combined alternating stresses, high-speed machines, in which different combinations of plane bending and torsion can be applied, have been constructed. Various plain and alloy steels and cast crankshaft materials are under examination.

Investigation is being made into the industrial applications of air injectors with reference to their use in maintaining air streams laden with granular matter. An experimental pneumatic conveyor has been constructed and experiments are being carried out to determine its performance.

The Department is investigating the principles underlying the design of satisfactory pipe-line joints capable of withstanding high temperatures and pressures. The work entails the study of the behaviour of flanged joints under pressure at air temperature, and at high temperatures, and measurements of bolt creep. The equipment permits tests to be made on 8-in. pipe flanges at temperatures up to 1,000° F. and at steam pressures up to 1,400 lb. per sq. inch.

A number of lubrication problems are receiving attention. Mention may be made of research on the aspect angle and attitude of a journal bearing under varying load, speed, clearance and temperature, and experiments on the effect of running in a clearance bearing at the seizing temperature of oils. Sensitive apparatus has been developed for measurement of the profile of bushes to determine the change of shape caused by running.

In the Metallurgy Department the production of iron of a high degree of purity has been achieved by the direct reduction of pure iron oxide in hydrogen. Specimens with a purity of the order of 99·99 per cent and of great softness and ductility were exhibited.

In view of the importance of oxide surface films in connexion with the problem of removing gases from molten metals, a systematic examination of the structure of such films is in progress by means of electron beam diffraction methods. The work has been extended to the study of oxide films formed on solid metals and alloys under atmospheric conditions and at high temperatures.

Considerable work is being carried out on the production of magnesium alloys, with the view of developing alloys stronger than those at present available for use at ordinary and at elevated temperatures. The microstructure, constitution and rolling and mechanical properties of various magnesium alloys are being investigated. The difficulty experienced in rolling and forging many of these alloys has been largely surmounted by slow pressing at high temperatures. A new experimental slow-speed rolling mill has been installed for use in breaking down the cast ingots.

In the Aerodynamics Department problems relating to the landing and take-off of aircraft are receiving attention. The work is of a two-fold character. The effect of landing flaps on stability near stalling incidence is being examined by means of the rolling balance. Measurements are made of the tendency of various wing sections, fitted with flaps and mounted on the balance, to accelerate or diminish rolling motion. The effect of proximity to the ground on the forces acting on an aeroplane is

also under investigation. Systematic measurements are made of the lift, drag and pitching moment of models at various distances from the ground.

Research is being carried out on the effects of gusts on the stresses in aircraft, and apparatus has been designed for recording the changes in vertical wind velocity in a gust. The use of this apparatus in conjunction with a recording anemometer measuring the mean horizontal wind speed, gives sufficient information to permit the effect of the gust to be predicted.

The performance of a number of high-pitch airscrews covering a wide range of pitch/diameter ratio has been measured and the results have been correlated with modern airscrew theory. Examination is now being made, by means of the hot spot method of flow photography, of the periodic flow through such airscrews, with the view of obtaining a direct experimental check of the basic assumptions of theory.

In the William Froude Laboratory, the effect of waves on ship resistance and propulsive efficiency together with the influence of hull form on this problem is under investigation. Demonstrations were given with a self-propelled model of a high-speed, twin-screw vessel. The speed, the propeller thrust, the amount of pitching and heaving, and the power required to drive the model are automatically recorded during its passage through rough water.

A number of model propellers made of a special aluminium alloy developed in the William Froude Laboratory were exhibited, together with apparatus for conducting tests with model propellers in open water.

The British Waterworks Association

ANNUAL MEETING

THE annual meeting of the British Waterworks Association at Cambridge on June 26 was the occasion for a vigorous and outspoken presidential address by Prof. C. E. Inglis, who, after a brief but interesting account of the origin and early development of the University, reviewed the policy of successive Governments in the past in respect of water supply for the needs of the country, and made some caustic comments on the "futile process of appointing water Commissions and pigeon-holing their reports" which has been its chief characteristic. He added that he regretted to observe the reappearance of the "policy of procrastination which has blighted waterworks legislation for the past 60 years" in the recent announcement by the Minister of Health in the House of Commons that as a preliminary to water legislation of a general character, a Joint Committee of the House of Lords and the House of Commons was to be set up to report "on measures for the better conservation and organisation of water resources and supplies in England and Wales".

Four papers presented to the Conference were more or less technical in character. One on "Water Softening at Cambridge", jointly written by Dr. Suckling and Mr. Philip Porteous, described the particular nature of the water at Cambridge, and the method of softening adopted after full consideration of the relevant data. The Cambridge water, which is derived from the Chalk, a formation which outcrops in the southern half of the county, is stated to be "uniformly clear, bright and colourless" containing no iron or manganese in solution. "The total solids, magnesium content and permanent hardness are not unduly high and sodium salts are only sparingly present. The water is neutral in reaction, the content of carbonic acid is low and no corrosive tendency has been exhibited during many years of use." It is also of excellent organic and bacterial purity. Being convinced on these grounds that the desired degree of softening could be satisfactorily attained by either the lime or the base-exchange process, the final decision of the local water company in favour of the latter was made on the basis of financial and engineering considerations. Tabular analyses are given of the water before and after softening, the total hardness of the untreated water being 24·0 (temporary hardness, 17·5; permanent hardness, 6·5). After treatment and blending, the total hardness (entirely temporary) is 11·5. The softened water sent into supply is described as "clear, bright, colourless, odourless and palatable". The water-softening plant consists of six units, each of 9 ft. diameter, capable of delivering "zero hardness" water continuously at the rate of 16,000 gal. per hour for 10 hours, after which it is put out of commission for regeneration. Each cylinder contains about 10 tons (420 cu. ft.) of Doucil, a synthetic zeolite, and is supported on a 12-in. bed of graded gravel. The synthetic zeolite was chosen in comparison with natural zeolite on financial and engineering grounds as in the case of the process. The salt consumption for regeneration is guaranteed not to exceed a rate 5,600 lb. per million gallons of water softened to zero hardness.

The paper by Mr. Philip Ulyott on "Biological Research in Relation to Water Supply" was a brief statement of the results of modern investigation in the subject, and of the sequence of events connected with plant life in an aqueous environment. A lengthy paper, full of interest from the historical and engineering point of view, was contributed by Mr. H. C. Darby on "Windmill Drainage in the Bedford Level" in the southern part of the Fens. Writing in 1748, Thomas Neale states that "there are now no less than two hundred and fifty [windmills] in the Middle Level. In Whittlesey parish alone I was told by some of the principal inhabitants there are more than fifty mills and there are, I believe, as many in Donnington with its members. I myself, riding very lately from Ramsey to Holme, about six miles across the Fens, counted forty in my view." But, as Mr. Darby points out, the windmill was a "wayward co-operator at the mercy of wind and gale and frost and calm. It was never powerful and it never provided a satisfactory solution to the problem of clearing water from the drains." Finally, there was a paper of a financial and administrative character by Mr. T. G. Rose on "Modern Methods of Management Control".

Petroleum Industry of France

MR. VICTOR FORBIN'S recent article on the French petroleum industry (*La Nature*, No. 2952, 385–396, May 1, 1935) is in effect an unanswerable vindication of France's claim to recognition as a petroleum power in the world to-day. Admittedly, at the beginning of this century and during the great development of the world petroleum industry, actuated by invention and universal adoption of the internal combustion engine, France had little right to recognition, for at this time tariff protection had been withdrawn and she was only able to supply 10 per cent of her domestic requirements of petroleum and products. This position was more or less maintained until 1925, when l'Office National des Combustibles Liquides was founded to give expression to the French desire "de devenir une puissance pétrolière". Close co-operation between this body and the Government led to drastic reorganisation of the entire industry and finally, in 1928, to the passing of a law which is now regarded as the charter of the French petroleum industry.

Under the new regime initiated by this law, authorisations were granted for importation and refining of crude petroleum in France for periods up to twenty years. Eleven industrial concerns contributed capital amounting to nearly 3,000 million francs for the erection of refineries at suitable places along the coast. Thus France acquired at Le Havre, at the mouths of the Rivers Loire, Gironde and Rhône, etc., some of, perhaps, the most modern refineries in the world. Systematic co-operation within the industry and far-seeing dispensation of resources led to the optimum equipment of each refinery for some particular type of raw material. Some are capable of producing the whole range of petroleum products, while others confine their activities to production of petrol, kerosene, gas-oil, etc.; throughout the industry there is a whole-hearted spirit of co-operation and a common desire that France should have a petroleum industry comparable with that of other nations.

France is now definitely reaping the benefit of this far-sighted policy initiated some five years ago, for when the first consignment of Iraq oil was conveyed by the pipe line to Tripoli in August 1934, there were new tank-ships ready for its conveyance to Le Havre and everything was in readiness for its reception. During the last five months of 1934, after completion of both branches of the Iraq pipe line, 600,000 tons of crude oil were exported from the twin ports of Tripoli and Haifa, 520,000 tons of which were destined for France. In 1934 French refineries treated 3¼ million tons of raw material, and it is estimated that this quantity will be increased to 4 million tons in 1935, as compared with 1,034,819 tons in 1932 and 2,739,305 tons in 1933.

During the first eight months of 1934, France exported 28,647 tons of kerosene and 682,292 tons of gasoline to Great Britain, Switzerland, Italy and other countries. These facts and figures should confute those who are still under the impression that the French petroleum industry is directed by foreigners.

Pollination Mechanism in Conifers

PROF. JOSEPH DOYLE and Miss Mary O'Leary have published (*Sci. Proc. Roy. Dublin Soc.*, 21, N.S., Nos. 19, 20 and 21, February 1935) a series of papers upon the pollination mechanisms in conifers. Their researches include records of intensive observations in the field, which are interpreted most interestingly in the light of the wide knowledge of the senior author of the comparative morphology of the reproductive structures in the group.

The authors point out that our knowledge of the movement of pollen on to the nucellus in *Pinus* has so far rested upon second-hand statements, most of them derived from some incidental observations by Strasburger. Strasburger appears to have assumed, on the basis of other well-known cases, that a fertilisation drop was formed and, in view of their turgid transparent appearance, to have ascribed its formation to the two characteristic prolongations of the integument beyond the micropyle.

As the result of very patient investigation, the Irish observers have at last seen this fertilisation drop—but at 2 a.m. in the morning—and by 7.30 a.m. every ovule is dry! This secretion appears to come from the nucellus, and though at night it may be found in almost every mature unfertilised ovule as it wells out of the micropyle and part of the way along the micropylar projection, it usually soon picks up some pollen grains from these arms. When these are immersed in the fluid, in the inverted ovule, they rapidly float with their winged surface uppermost on to the nucellus; the grain is thus brought against the nucellus with the surface towards it through which the pollen tube emerges. More remarkable still, within ten minutes of the grain being thus transferred to the nucellus, the drop is once more reabsorbed while it still remains in the unpollinated ovule. The authors have tested this by introducing pollen into the drop at night. They argue cogently that the function thus suggested for the winged expansions to the pollen grain is much more reasonable than its use for transport of the grains in the air, as the larger grains of *Larix* and *Pseudotsuga* are without wings.

On the other hand, the authors have to solve the problem how these wingless pollen grains of *Larix* also reach the surface of an inverted ovule. In *Saxegothœa* and *Cedrus* they describe the germination of pollen grains well away from the micropyle and their growth to the nucellus: they also figure and discuss the function of the stigma-like projections in the integuments of *Pseudotsuga* and *Larix*. These papers are full of stimulating discussion of new data that are a permanent contribution to our knowledge of the pollination mechanisms of the conifer.

Educational Topics and Events

EDINBURGH.—At the graduation ceremony on June 28, the honorary degree of LL.D. was conferred on the following: The Right Hon. the Viscount Bledisloe, Governor-General and Commander-in-Chief of New Zealand; Dr. J. L. Garvin, editor of the *Observer*; Dame Maria M. Ogilvie Gordon, geologist and vice-president of the International Council of Women; Prof. J. Graham Kerr, M.P., regius professor of zoology in the University of Glasgow; Prof. John Laird, regius professor of moral philosophy in the University of Aberdeen; Sir George Macdonald, formerly secretary of the Scottish Education Department, archæologist, numismatist and historian; Dr. J. D. Pollock, Hon. Surgeon-Commander, R.N.V.R.; The Hon. Lord St. Vigeans, formerly chairman of the Scottish Land Court.

The degree of D.Sc. was conferred on the following, for the theses indicated: A. B. D. Cassie ("Infra-Red Absorption Spectra and Molecular Structure of Triatomic Molecules"); D. Clouston ("The Identification of Grasses by Leaf Anatomy"); Dr. J. MacLeod ("The Ecological Complex controlling Activities and Distribution of *Ixodes ricinus*"); Dr. H. W. Melville ("The Kinetics of Gaseous Chain Reactions").

OXFORD.—Sir Charles Sherrington has resigned the Waynflete chair of physiology, which he has held since 1913, as from October 1.

Mr. L. S. Bosanquet has been granted the degree of D.Sc.

At Christ Church, Mr. D. Roaf has been elected to the Duke of Westminster research studentship (that is, fellowship) for work in nuclear physics, and Mr. J. A. Moy Thomas to a lectureship for research in vertebrate palæontology.

At the Queen's College, Mr. E. W. Yemm has been elected to a junior research fellowship in botany.

DR. JOHN A. WHEELER has been appointed assistant professor of physics in the University of North Carolina, at Chapel Hill. During the past year, Dr. Wheeler has pursued research in nuclear physics at the Institute of Theoretical Physics in Copenhagen.

GERMAN universities are, one gathers, like other cultural institutions in Germany, being remoulded so as to conform with Nazi aims. A letter from the Berlin correspondent of the American Medical Association tells of a new decree releasing the general student body from obligatory attendance on the special political training course prescribed, together with enrolment in a hostel, for members of the Nazi student league. The director of this league has announced that "during the past year and a half the student has been tossed about to such an extent that he has lost most of his faith in attempts to direct the thinking of students. A reawakening of this faith I regard as a necessity . . ." Last winter new regulations made compulsory for all students participation in physical exercises and sports, including *fünfkampf* training and rifle exercise during the first three semesters as a pre-requisite for any degree. Another interesting development is the provision made for permitting twenty of the most talented sons of workmen to attend a university without presenting a diploma of completion of a secondary school course. For such special entry the Universities of Heidelberg and Königsberg are being considered.

SEX education in schools is discussed in a remarkable paper by Dr. E. P. Phillips which has been published by the Transvaal Education Department in its monthly circular for April. Dr. Phillips writes as a biologist. He begins by emphasising the fact that notwithstanding the fundamental biological discoveries of the past seventy-five years, we still think in terms handed down to us by earlier civilisations, terms involving an often inextricable entanglement of religious ideas with ideas relating to sex. Hence arise divergences between mental outlooks which he classifies as the orthodox religious, the biologist's, and that of the large body of parents who, while not holding very strict religious views, are ignorant of the elements of biology. There should, he holds, be no course of sex education *as a subject*, taught either by the school staff or by visiting doctors; but all children should receive instruction, which should begin before the age of puberty, in some of the more important biological facts about themselves as human beings. It should be inculcated that mankind is faced, like myriads of other species, with the two fundamental problems—the struggle for individual existence and the struggle to maintain the species. Thereafter, the similarity of mankind to the rest of the animal kingdom having been sufficiently demonstrated, the overwhelming importance of the reasoning faculty which differentiates the human from other species should be stressed in connexion with man's social development. To adolescents who have received such a grounding, information about the dangers and implications of sex can be imparted without difficulty. The crux of the scheme for such a broad biological course is the supply of suitable teachers. These should have studied biology, chemistry, physics and geology, should have read widely, and should have tact, sympathy and understanding. The course should not be taught as an examination subject, thereby suppressing the individuality of the teacher. It should be a necessary part of every child's social, moral, ethical and religious training.

Science News a Century Ago

Lyell and Sir John Herschel

LYELL, whose "Principles of Geology" had been published originally in three volumes in 1830, 1832 and 1833 respectively and had been republished in four volumes in 1834, wrote to Sir John Herschel on July 6, 1835: "I heard some months ago from Whewell that you had, in one of your letters to him, expressed much pleasure at some parts of my book, which I think you read when on your way to the Cape. It has been so much altered, enlarged, illustrated, abridged, and I hope improved since the first edition, that I am anxious, if you ever refer to it again, that you should see it in its amended state. Some of my friends have read letters of yours which they have received, to me, and I rejoice that your grand scheme of visiting the Southern Hemisphere has answered so well."

"When at Copenhagen last year Oersted, who was reading your paper on double stars, was talking of

it continually, and trying to make me understand the *poetry* of some speculations, which only amused me, from seeing that it was deep mathematics with which he was delighted, as with a romance."

"Murray has sold 1,750 copies of my book in the last ten months, so that I have the satisfaction of being much read. . . ."

The Science of Education

AN advertisement in *The Times* for July 6, 1835, ran as follows: "A Course of Seven Lectures on the Science of Education will be delivered in Willis's great Rooms, 26 King-street, St. James's, commencing tomorrow the 7th of July at 3 o'clock, and continued on Tuesdays, Thursdays and Saturdays at the same hour, by the Rev. R. J. Bryce, LL.D., Principal of the Belfast Academy. The object of these lectures is to reduce the art of teaching and managing children to scientific principles, derived from the known laws of the human mind; to point out the best methods in each department of education; and to show the means of varying those methods to correspond with the endless varieties which occur in the minds of children. The formation of such a science of education has been spoken of as a great desideratum by the most eminent philosophers of modern times, and has long been anxiously wished for by the most distinguished friends of education. . . . The proceeds of the lectures, after paying necessary expenses, will be placed at the disposal of a committee of the audience, to be by them applied to the promotion of some object connected with the improvement of education."

J. D. Forbes in the Pyrenees

THE travels of Prof. J. D. Forbes began when, as a boy of sixteen years of age, he visited France, Germany and Italy. This journey led to the publication of his first scientific memoir, "Remarks on Mount Vesuvius", which appeared anonymously in the *Edinburgh Journal of Science*. Six years later, in 1832, he first visited Switzerland, from which he hastened home to enter successfully for the chair of natural philosophy at Edinburgh. His favourite subject was heat, and in the summer of 1835 he set out to study the hot springs of the Pyrenean valleys. His letters and journal contain many interesting observations on his travels. On July 7, 1835, he went from Bordeaux to Pau by diligence and on July 9 he records: "A splendid morning. . . . The whole range of the Hautes Pyrenées was now uncovered, and presented as noble and rugged an outline as I ever saw. . . ." He then went to Eaux-Bonnes and to Eaux-Chaudes with its splendid gorge. "If ever there was a valley of disruption," he wrote, "it is this one, though I do not pretend always to decide. This confirms Dr. Daubeny's theory of hot springs, especially as these waters issue just at the junction of the granite and limestone. The limestone rises always to the granite, more as it approaches it, and at last is elevated in horizontal strata on the top of it—at least so far as I can judge from a very imperfect examination. What confirms the view of the granite being the upheaving agent is that the valley of disruption is perpendicular in direction to the strata (Hopkins' theory). It is remarkable that there are signs of water wearing (obviously not weathering) on the rocks at a great height above the torrent."

Societies and Academies

LONDON

Royal Society, June 27. W. A. BONE, R. P. FRASER, and W. H. WHEELER: A photographic investigation of flame movement in gaseous explosions. A new view of the detonation wave in gaseous explosions is advanced. It can no longer be regarded as simply a homogeneous shock wave in which an abrupt change in pressure in the vicinity of the wave-front is maintained by the adiabatic combustion of the explosive medium through which it is propagated, but it must now be viewed as a more or less stable association, or coalescence, of two separate and separable components, namely, of an intensively radiating flame-front, with an invisible shock wave immediately ahead of it. According to the new view, detonation in an explosive gaseous medium is the propagation through it, as a wave, of a condition of intensive combustion, initiated and maintained in a shock wave by radiation from an associated flame-front; and spin ensues whenever the conditions are such that the radiation from an attenuated flame-front causes a localised intensive excitation of molecules in the shock wave just ahead of it. The experimental part of the work has been mainly concerned with detonations in a moist $2CO+O_2$ medium, which has proved to be specially adapted to the elucidation of the dual character of the phenomenon. O. H. LATTER and H. ELTRINGHAM: The epigamic behaviour of *Euploea (crastia) core asela*, Moore (Lepidoptera, Danainæ) with a description of the structure of the scent organs. Observations in the field show that the male butterfly diffuses, from brushes exserted from the abdomen, a scent which attracts females from a distance. While male scent organs of great complexity are found in many insects, no evidence has previously been obtained of the distant action of such organs, termed here 'telegamic'. B. F. J. SCHONLAND, D. J. MALAN, and H. COLLENS: Progressive lightning (2). A general account, based on the study of 95 flashes photographed with the Boys and other cameras, is given of the mode of development of the lightning discharge. It is shown that the leader-return stroke sequence is present in almost all the cases examined. Leaders to first strokes are stepped, those to subsequent strokes generally dart-like. In certain cases of very slow dart leaders, these change to the stepped form at their lower ends. Slower leader velocities and higher intensities of return strokes are associated with longer time-intervals between strokes and their predecessors; hence the degree of pre-existing ionisation in the channel governs the velocity of the dart-leader. The downward-branching of lightning and its characteristic zig-zag form arise during the stepped leader process before the first return stroke.

PARIS

Academy of Sciences, May 20 (*C.R.*, 200, 1697–1804). CHARLES ACHARD and AUGUSTIN BOUTARIC: The physicochemical study of the changes undergone by the blood serum under the influence of heat. The diluted serum is treated with charcoal, and the quantity of the latter determined which completely removes the colloidal substances, use being made of the surface tension. Data are given for results obtained by heating for various times at temperatures between 55° C. and 62° C. PIERRE WEISS: The

equation of state of fluids? The negative internal pressure at high temperatures. CHARLES NICOLLE and MME. HÉLÈNE SPARROW: Infection by the conjunctiva of small apes with the murin I typhus virus from Tunisian rats. JEAN MIRGUET: The continuity of the biparatingent. PAUL ALEXANDROFF: Suites of topological spaces. ADOLPHE BUHL: The integral of Stieltjes. LADISLAS FEJES: Cauchy's exponential series. N. GÜNTHER: The resolvant of certain integral Hermite equations. A. KOLMOGOROFF: The Laplace transformation in linear spaces. JEAN BRAÏTZEFF: The fundamental formula of the theory of Dirichlet's series. FLORIN VASILESCO: Remarks on the various methods of solution of the problem of Dirichlet. PAUL LÉVY: A tensorial form of the functional differential equations of Green's and Neumann's functions. LÉON BRILLOUIN: The transversal physical waves in wave mechanics and the harmonic oscillator in four dimensions. PAUL BERNARD: The measurement of the pressures developed by explosive substances. A comparison of crusher pressures with true pressures measured by a piezoelectric dynamometer. The results with a light and heavy piston in the crusher manometer are compared graphically. DANIEL BARBIER, DANIEL CHALONGE and ETIENNE VASSY: The interpretation of the continuous absorption of hydrogen in stars of early spectral types. AUREL POTOP: The thermal conductivity of metals examined in the form of small bars. JACQUES VAN MIEGHEM: The velocity of transport of electromagnetic energy. CHARLES BÉCHARD: The electrolytic deposit of alloys of copper and tin. PIERRE SÜE: The conductivity and hydrolysis of the sodium niobates. The orthoniobate is completely hydrolysed: the salt, 7/6 Na_2O, Nb_2O_5, is strongly hydrolysed and in equilibrium with the metaniobate. AURELIAN NAHERNIAC: The study of a characteristic band of the OH group in the near infra-red. MME. LUCIE LEFEBVRE: The absorption spectrum of ozone in the region of the photographic infra-red. The tubes employed were equivalent to a column of 50 cm. of pure ozone: the region explored was between 6500 A. and 10,000 A. EMILE SEVIN: The play of waves, spin and numbers. PIERRE AUGER, LOUIS LEPRINCE-RINGUET and PAUL EHRENFEST: The absorption of the soft fraction of the cosmic corpuscular radiation. An account of results obtained at the International Laboratory at the Jungfraujoch. FRANCIS PERRIN: The mechanism of the capture of slow neutrons by light nuclei. MME. L. S. MATHIEU-LÉVY: The influence of complex formation on the adsorption of copper in ammoniacal solutions by precipitated ferric hydroxide. MLLE. M. QUINTIN: The application of Debye's theory to solutions of cadmium chloride. CHARLES TOURNEUR: Study of the action exercised by alcohol on gum arabic sols, as shown by the polarisation of the diffused light. ARAKEL TCHAKIRIAN and HENRI VOLKRINGER: The Raman spectra of the bromine compounds of germanium and of tin. Comparative diagrams are given of the Raman spectra of the compounds RBr_4 and $RHBr_3$, where R is carbon, silicon, germanium or tin. AUGUSTIN MACHÉ: Contribution to the study of the determination of ozone. Comparisons of the iodide and fluorescin methods. For low concentrations of ozone the latter is more accurate. A. P. ROLLET: The potassium borates. Study of the system B_2O_3, K_2O. MAURICE BILLY and PAUL BRASSEUR: The preparation of anhydrous titanium trichloride. The tetrachloride is reduced with precipitated antimony, afterwards removing the excess of tetrachloride with carbon tetrachloride and the antimony chloride with anhydrous ether. PIERRE CARRÉ and HENRI PASSEDOUET: The relative mobilities of the normal primary alkyl groups from C_1 to C_{16} in their chloroformates. G. MULLER: The oxidation of mineral oils by gaseous oxygen at moderate temperatures. The chemical nature of the oxidation of mineral oils is the same whatever their origin or previous treatment, although the amount of deposit may vary considerably. The white refined oils are most strongly oxidised. ALEXANDRE DINCA-SAMURACAS: The polarisation of seismic waves in the primary phase of earthquakes. LOUIS FAGE: The localisation in the intermediate waters of the Pacific of the little-known *Ceratolepis hamata*. A single specimen of this organism was collected by the *Challenger* between the New Hebrides and Australia. During the last voyage of the *Dana* in the Pacific, Schmidt was able to collect nearly two hundred specimens of this Crustacean. The results obtained from this material are given, completing the description given by Sars of the *Challenger* specimen. M. BURGAUD: Magnetic observations in the south and south-west of China and a map of the isogonics and isodynamic lines. LOUIS EMBERGER: New botanical researches in the eastern Grand Atlas. JEAN CHAZE and ANDRÉ SARAZIN: The parasitism of mushroom beds by the mole is a reversible phenomenon. ARMAND DEHORNE: The anatomical and cytological characters of the thoracic nephridia of *Sabellaria*. PAUL MATHIAS: The evolutive cycle of a holostomid trematode, *Cyathocotyle Gravieri*. OCTAVE DUBOSCQ and MLLE. ODETTE TUZET: A new stage of development of the calcareous sponges. GEORGES UNGAR and MLLE. MARIE ROSE ZERLING: The intervention of a humoral transmission in vasodilatation known as antidromic. Arguments in favour of the existence of histaminergic nerves. MME. VÉRA DANTCHAKOFF: The equivalence of the somatic tissues in the gonads of the fowl. PIERRE GRABAR and ANDRÉ RIEGERT: The nature of urease: approach to the study with the aid of fractional ultra-filtration. The activity of urease is intimately connected with very bulky molecules of protein nature: Sumner's crystallised urease, in aqueous solution, was the most homogeneous of the preparations studied. AUGUSTE and RENÉ SARTORY, JACQUES MEYER and FRÉDÉRIC ARNOLD: Comparative attempts at the determination of the phosphorus and potassium contained in an arable soil by means of Hilgard's chemical method. Neubauer's biological method and that of Niklas, utilising *Sterigmatocystis nigra*. The Niklas method is very suitable for determining the immediate requirements of a soil. CONSTANTIN LEVADITI and JEAN VIEUCHANGE: The inoculability of certain neurotrope viruses (herpes, poliomyelitis) through the external auditory canal.

VIENNA

Academy of Sciences, May 9. F. WESSELY, K. DINJASKI, W. ISEMAN and G. SINGER: Bitter principles of kolombo root—kolumbin. G. KIRSCH: Viscosity and melting curves. E. HASCHEK and H. MACHE: Dependency of spark-noise on the electrode material with a rapid succession of sparks. E. CHWALLA: Bulging of rhomboidal plates under pressure and shear loading. W. PASSER: Pressure distribution through an elastic layer. W. W. LEPESCHKIN: Fundamental substances of living matter (vitaids) and their significance in biology.

The importance of 'vitaids' to life is probably due to the part they play in the structure of the consistent phase of the protoplasm. F. ROCH and F. MOLL: New terenid species. F. HERITSCH: Uppermost lower Devonian and lower mid-Devonian. A. THURNER: Position of the Trias in the mountains around Murau. O. GUGENBERGER: The Cardita layers of Launsdorf in mid-Carinthia and their fauna. H. REBEL: Lepidoptera from the Ægean Islands. F. WERNER *et al.*: Insects and arachnoids of the Ægean Islands. L. FLAMM: Algebraic electrodynamics. A. SKRABAL: Chemical induction. In continuation of investigations on the kinetics of intermediate reactions, those general systems are considered which can be decomposed into separate systems with different total reactions. M. PESTEMER and L. WILIGUT: Ultra-violet absorption of certain aromatic hydrocarbons (3); constitution of tetrahydrodiphenyl. Substances with double linkings conjugated to the benzene nucleus show a marked increase in the extinction, whereas the extinction of the benzene bands is not increased by substitution with alkylenes or olefines in which the double linking is separated from the benzene nucleus by more than one carbon atom. From this it follows that the tetrahydrodiphenyl obtained by hydrogenation of diphenyl has the constitution of the known 1-phenylhexene-1. E. ABEL and J. PROISL: Mechanism of the lead-chamber reaction (1); reaction between sulphurous and nitrous acids in the dilute system. A. PONGRATZ and G. MARKGRAF: Perylene and its derivatives (44). A. VERDINO and E. SCHADENDORFF: Condensations of ethyl chlorocarboxychlorate with amines and phenols. W. KOSMATH: Process for measuring the momentary radon content of the open air at spas with radioactive waters. Use is made of the arrangement previously described, which consists essentially of two similar cylindrical air-tight ionisation chambers (measuring chamber and compensation chamber) of about 9 litres capacity, and a Lindemann electrometer with switch-box. T. KORMOS: Revision of the small mammal remains of Hundsheim. A. WAGNER: Daily course of cosmic ultra-radiation. A reply is made to Hess's criticisms of the author's previous communication. A. FINK, P. GROSS and H. STEINER: Conductivity of strong acids in mixtures of heavy and light water. Determinations have been made of the conductivities of hydrochloric and perchloric acids in about 0·01 *N* solutions in mixtures of heavy and light water at 18° C. The value of the equivalent conductivity of hydrochloric acid at infinite dilution falls from 377 to 250 in pure deuterium oxide, the fall being non-linear. K. UNNA and L. WALTERSKIRCHEN: Action of anti-diuretic pituitary hormone on dogs to which water is or is not given.

Scientific Management and Social Problems

THE sixth International Conference on Scientific Management, which opens on July 15, comes at a time when the whole contribution of science not merely to industrial efficiency but also to every aspect of national and social welfare is receiving a searching examination. While on one hand there is a growing recognition that readjustments are required in our political and economic policies to enable us to take full human advantage of this age of science, technology and power production, while most people are disposed to regard a shorter working day or a shorter working week as an inevitable consequence of technological advance and as a desirable if not essential means of securing a wider distribution of leisure, there are strong forces setting in exactly the opposite direction.

The recognition that social control has not kept pace with the social change induced by scientific research and its applications has not always stimulated a resolve to use the full powers of the economy of science, technology and power production which man's genius has created. On the contrary, it has also induced the rise of a defeatism spirit which deliberately renounces many of the advantages with which the application of scientific thought and discovery can endow mankind, and attempts to return to the methods and conditions of the past. There is, in fact, a grave danger of a widespread revolt against science and of a social throttling of research, and the warning of Glenn Frank in "America's Hour of Decision" has a validity far beyond that of the American position of which he was particularly writing.

The obvious futility of attempting to set back the clock of progress should not lead scientific workers into the error of rejecting such warnings superficially. It must be recognised that, in the new civilisation created under the impact of science and technology, social change has so far outstripped institutional change that the survival of our social order has been in serious doubt in more countries than one. Neither a people nor a Government can be hastily condemned if under such conditions it clutches at any method to avert disaster. The task of the scientific worker is thus that of endeavouring to show a more effective alternative. What is required is a concerted effort by scientific workers, in physical and in social science, to plan the prosecution and publication of their research so that the scientific progress of the next twenty-five years shall stabilise and enrich the life of the nation instead of producing further social instability.

The views advanced by Glenn Frank on the situation in the United States deserve the more serious attention because in some countries scientific workers have already lost the freedom which they still enjoy in English speaking countries. Scientific workers must face the fact that the production of new knowledge cannot be regarded as automatically and invariably good. They must also recognise that the responsibility for considering the impact of modern science in modern society is not solely the responsibility of the worker in social science. It is equally the responsibility of the worker in physical science, and careless distinction between social and physical sciences is in fact one of our most serious dangers.

This changed attitude to science is due essentially to factors the influence of which is widespread. A growing dissatisfaction with maladjustments in society, and with the strain on the structure and functions of the political, social and economic

order due to *laissez-faire*, is accompanied by a growing disillusionment with research in which the production of new knowledge is unaccompanied by more effective effort to prevent its application causing more troubles than it cures. These factors alone, according to Dr. Frank, have been even more instrumental than financial stringency in determining the curtailment of expenditure on research in the United States of America in the last two or three years.

The third factor in this attitude to science, the determination to secure better planning and control of political, social and economic developments, enforces the necessity for more effective co-operation between scientific workers themselves. Earlier consideration of the political, social and economic effects of discoveries in the physical sciences or in industrial technology can only be secured by such co-operation. If we are to shorten to any adequate extent the dangerous time lag between the swiftly changing processes of industry and our slowly changing policies, we must develop some means of setting social science to work from the beginning, before social and economic havoc has been produced.

This may well prove an ideal which we cannot entirely realise. However, if it were possible to shorten by even a decade the time lag between technological development and developments in social or economic policy, much would have been done to alleviate distress and maladjustment and to mitigate the opposition to the spread of science. An advance of this kind presupposes the extensive application of scientific thought and methods to fields where they have scarcely begun to penetrate. It is, principally, over-specialised education which has left us so ill-fitted for the mastery of the problems of social management confronting us to-day.

The full significance of the International Conference for Scientific Management can only be appreciated against such a background as this, in the light of a well-founded determination for better planning and more effective control over the whole field of industry and politics, even if there is implied some restraint of scientific effort or change in its direction. Moreover, there are two basic questions on which the Conference may be expected to throw authoritative light and with which its programme indicates it will deal in some measure.

The first of these questions is that of the training of administrators and of securing an adequate and continuous supply of administrators of the requisite quality. The practice of scientific management depends primarily upon the capacity of the administrator, and if the general level of administration whether in industry or the State is to be raised, we cannot continue to rely upon those fortuitous methods of filling the higher managerial posts which have hitherto been the vogue in most industrial and commercial organisations in Great Britain. Some definite efforts must be made to secure a reservoir of personnel with sufficient initial training and experience to form the starting-point for selection for promotion to the higher ranks. This must be supplemented by systematic attempts on scientific lines to select from this reservoir those who give the most promise of qualifying for the higher administrative positions, and to ensure that they receive opportunities for further experience and training where required.

The maintenance of progressive prosperity depends largely on the continuous succession of able administrative leaders. It is also linked with the related problem of the place of the expert in modern government. Here, although in some sections of industry it may be fairly claimed that an adequate solution has been found, in social and political affairs the problem has received nothing like the same attention. All too frequently either the expert is allowed to usurp the place of the administrator and dictate policy to the neglect of other factors and the detriment of management, or, especially where the scientific expert is concerned, the administrator has proved incompetent or indifferent to the scientific factors involved.

It may be taken as axiomatic to-day that statesmanship must rest upon a scientific study of the causes of social problems and a statistical study of the results of social policies. The correlation of expert opinion and knowledge with legislative and executive leadership does not mean that policy should be determined primarily by expert advice. The expert is essentially a specialist in means, not in ends. He indicates the facts upon which a wise decision or policy must be based. As Dr. Glenn Frank points out, "the function of the expert is that of hewer of wood and drawer of water to the statesman". It is the latter whose patience and sense of social needs, values and possibilities, added to a knowledge of the facts, enable him to build up the broad policies required.

The real question at issue is how to provide administrators possessing at once the sense of values and the capacity to assess and interpret the

increasingly technical factors involved in almost every Government decision. The sessions at the Conference to be devoted to management problems arising from Government intervention can scarcely avoid the consideration of this particular question. A certain degree of scientific objectivity at any rate must be secured in public policy, and whether a new orientation of the methods of government as suggested by General Smuts is required, or whether the question is rather one of redressing the educational situation so as to ensure an adequate reservoir of administrators competent to assess scientific and technical factors in government, the matter is one urgently demanding serious study. Only in this way can we attain either the power or the vision to control the forces now at our disposal so as to ensure the maximum advantage to mankind. No less here than in other branches of human endeavour, the fullest freedom to creative thought and effort is an essential element in success, and indeed the only alternative to the renunciation and defeatism already characterising certain nations in this struggle to-day.

Notable Epidemics and their Causes

Some Notable Epidemics

By Dr. H. Harold Scott. Pp. xix + 272. (London: Edward Arnold and Co., 1934.) 12*s*. 6*d*. net.

EPIDEMIOLOGY, after making slow but steady progress for a century or more in Great Britain, as the outcome of the work of the disciples of Sydenham—the so-called 'Annalists'—sustained a severe setback when the Industrial Revolution, with its crowding and neglect of sanitation, facilitated the spread of disease. Dr. John Snow's investigations into the cholera of 1848–49 may thus be said to have inaugurated a new era, making water-borne infection an established reality, and this stimulus, following upon the work of Mead, Pringle, Lind, Baker, Blane, Jenner, Thackrah and the three reports of the Poor Law Commissioners of 1838–39, greatly strengthened the hands of Chadwick and Simon in producing the health crusade of the latter half of the nineteenth century. Almost inevitably, therefore, Dr. Scott's Chapter i commences with an account of the "Broad St. Pump Outbreak" (1854).

It is, perchance, the 'irony of fate' which has determined that Snow's spade-work on this Westminster prevalence, followed as it was by Snow's and Simon's reports on the "Southwark and Vauxhall Water Outbreak" of 1854 and by Netten Radcliffe's report on the "East London Cholera Outbreak" of 1866, firmly established the belief in water-borne disease. There can be no surprise, however, at Sir John Simon's difficulty in accepting "Snow's peculiar doctrine", or his reserve regarding deductions drawn from reports on the cholera prevalences of 1854 and 1866.

A probable explanation of the difficulties in question, as resulting from failure to recognise the possibility of contemporaneous spread by shellfish, appeared in *Public Health* (Jan. 1923, pp. 98–106); moreover, as regards "The Pump", the official inquiry made at the bidding of a Committee for Scientific Enquiries, in 1855, clearly showed that "many cases in the infected districts occurred of persons who were not in the habit of using the pump water". This Chapter i and Chapters ii–vi, in which Dr. Scott deals with water-borne outbreaks of typhoid fever, at Blackburn (1881), Worthing (1893), Maidstone (1897), Lincoln (1904–5) and Bolton upon Dearne (1921) make exceedingly interesting reading; though here, again, there is something to be said (see *Public Health*, Dec. 1921, pp. 57–59) for the view that other influences than the water supplies were also at fault. It must be remembered that some sixty or more years ago, a president of the Society of Engineers was able to trace all cases of typhoid fever coming under his notice, in London, to faulty drains; and that in similar fashion water supplies enjoyed an almost complete monopoly of discredit as regards cholera and typhoid fever for several decades.

Chapters vii–xv present intriguing problems of a like character with reference to milk outbreaks of typhoid fever, diphtheria and scarlet fever; though here the claim to a monopoly for the suspected milk is stronger as a rule than was the case in the water outbreaks—in the case of the "milk-borne enteric fever outbreak" in St. Marylebone (1873), at any rate, the anomalies are, indeed, very disturbing; scepticism was voiced, at the time of the prevalence, and the difficulties, regarding "nursery milk" and "extent of involvement of domestic servants", are instanced on p. 61 of the paper in *Public Health*, Dec. 1921, referred to above.

Chapters xiii and xiv, dealing with outbreaks in which milk infection was traced to disease in milch cows, are particularly interesting. Chapter xv also deals with a milk outbreak, and Chapter xvi with two food-poisoning outbreaks. Then comes the masterpiece, the late Dr. H. T. Bulstrode's report on the "Oysterborne Enteric Fever of the Winchester and Southampton Banquets", of 1902. Hecker (who by a misprint appears as Heckel on p. xi of Dr. Scott's book), the author of "Epidemics of the Middle Ages", commented on the fact that Nature, in isolated epidemics, "never displays herself in all her bearings", but he would doubtless have maintained that Nature very rarely displays herself in *one* solitary bearing. On reaching Dr. Scott's Chapter xvii, however, we come very near to monopoly of infective property by one article of food. Dr. H. T. Bulstrode's report on the two banquets covers the whole ground, leaves no stone unturned, and preceded and followed as it was by his masterly reports on "Oyster and Other Shell Fish Layings", it brought about the remarkable reduction of prevalence of typhoid fever in Great Britain, which is one of the outstanding achievements of public health effort.

Dr. Scott's concluding chapters describe "Outbreaks at Aberdeen, 1919–1926" and "Sonne Dysentery Outbreaks, Aberdeen 1925–26", "Sonne Dysentery Outbreaks at St. Andrews, 1926" and "Sonne Dysentery Outbreaks at St. Pancras and Holborn, 1933".

Prof. W. W. Jameson, in his preface to Dr. Scott's book, writes: "Dr. Scott has performed a real service in producing this book"; the original reports have been so fully described "that the student will lose little, if anything, through inability to refer to the original reports", many of which "are now difficult to obtain". He adds, however, that he hopes "Some may be stimulated to a closer study of those older Reports from which much of the material in this book has been drawn".

Dr. Scott's book calls to mind Wordsworth's poem on "The Solitary Reaper", who sings of "Old unhappy far off things and battles long ago". The reports of Dr. Scott's public health pioneers are not only replete with interest, but also they constitute the foundations upon which rests the preventive medicine of to-day. Surely, then, it may be hoped that Prof. Jameson's wish may materialise and that Dr. Scott's book may prove a great help in letting all budding medical officers of health know that which "Our Fathers have told us".

W. H. HAMER.

Structure of the Eastern Dolomites

Geologie von Cortina d' Ampezzo und Cadore. Von Dr. Maria M. Ogilvie Gordon. (Sonderabdruck aus dem Jahrbuch der Geologischen Bundesanstalt, Band 84, Heft 1–4.) Pp. 59–215+18 plates. (Wien: Geologische Bundesanstalt, 1934.) n.p.

THIS work describes the stratigraphy and tectonic structure of the Eastern Dolomites lying between Auronzo on the east and Caprile on the west and between the Drei Zinnen in the north and Cibiano in the south. It is illustrated by an excellent map (1 : 50,000) and by numerous explanatory sections. As stated by the author, greater attention is given to the tectonic structure than to the stratigraphy of the area.

Part 1 relates to the larger portion of the area lying east of the Ampezzo valley. Thirty-five pages are devoted to the stratigraphical succession between the Permian and the Upper Cretaceous, while eighty pages are devoted to the tectonic structure. The pre-Permian quartz-phyllites and the Grödner sandstone are limited to a small area east of Auronzo. The Bellerophon beds and the Werfener beds occupy a considerable area round Auronzo and Lorenzago, also in the Val-di-Cadore in the more denuded eastern margin; the author stresses the importance of Calcareous algæ and foraminifera in the formation of the limestones of the Bellerophon beds. The Mendola Dolomite also shows important algal development. The Upper Trias, notably the Schlern Dolomite and the Dachstein Dolomite, forms the whole of the central and northern portions of the district, and gives rise to important mountain cores with Wengen and Cassian beds clinging to their flanks (in the Cristallo, Sorapis, Marmarole, Antelao and Tofana groups), a few of these being capped by deposits of Lias and Cretaceous rocks.

In the description of the physical and tectonic structure, we are presented with a masterly account of the disturbances which the district has undergone. The detailed account of the various movements as deduced from the author's investigations and study of the work of previous writers makes fascinating reading, and the results are admirably depicted on the geological map and the diagrams accompanying the map.

The district appears to have been originally folded into a series of broad west-east anticlinal and synclinal folds, and these structures can still

be traced in the several strips in the central portion of the area, in the disposition of the mountain ranges composed of Dachstein Dolomite and in the significant anticlinal axis passing through the Tre-Croci Pass. Later movements, however, have disturbed the original simplicity of structure and bent up the mountain blocks into dish-shaped forms, notably the eastern margins of the Marmarole and Antelao. The main lines of movement were originally pointed out by Mojsisovics, and these and subsidiary lines of disturbance are described in detail by the author. The main lines have been given special names and have been traced more or less continuously through the district; they include both thrust-planes and normal and tear faults, indicating a general pressure from north to south. The most important lines are the Rauhtal line in the north, the Antelao line in the centre and the Val Sugana line in the south-east. The two former run in sinuous lines from west to east, while the last runs in a north-east–south-west direction in the neighbourhood of the Val-di-Cadore, and has given rise to a complicated series of tectonic structure. An interesting point is the association of valleys parallel to these lines of dislocation.

The second part of the work deals with the district west of the Ampezzo valley and contains also much of interest in connexion with the structure of the Tofana-Fannes group, the Pelmo range and the effects produced by the western continuation of the Antelao line of disturbance.

The author is to be congratulated on a fine piece of work which forms an important contribution to our knowledge of the structure of the Eastern Dolomites.

Progress of Physics

(2) The Physical Society. Reports on Progress in Physics

Pp. iv+371+2 plates. (London: The Physical Society, 1934.) To non-Fellows, 12*s.* 6*d.* net.

(1) "THIS conference," remarked the owner of one of the most famous names in the physical science of to-day, "is a very good conference—as conferences go." Approbation from Sir Hubert Stanley is high praise indeed, and certainly the conference which met in London in the first week of October 1934 was unique of its kind. Held under the joint auspices of the Physical Society and the International Union of Pure and Applied Physics, and concerned with topics among the most important of those about which physical science is conversant, it is small wonder that the conference held, for a week, the attention of some five or six hundred members, drawn from almost every European country and from America.

The report of the conference is worthy of the occasion. It is published in three volumes which deal respectively with the solid state, with the present position of nuclear physics, and with certain problems of units and of nomenclature which have been discussed by the Symbols, Units and Nomenclature Committee of the International Union.

Conference reports are apt to be disjointed and—it must be confessed—lifeless; the present volumes are a pleasant exception. The topics are vividly interesting, and the programme has been developed in such a way as to show a very satisfactory coherence in the arrangement of the subjects.

Moreover, the great difficulty which faces the editors and readers is, in this instance, missing. Most readers who are not specialists in a particular branch of physics find that a major difficulty in following the papers presented is due to the authors' bad habit of plunging without apology *in medias res*, assuming in their readers a specialised knowledge which comparatively few possess. It is relatively easy to avoid this. A general introductory survey, indeed in many cases a few sentences of introductory matter, may make all the difference. Specialised matter is not always so esoteric as the non-specialist may suppose—clarity of thought and of expression, the art of beginning at the beginning, a kindly feeling for the other fellow—these are gifts that go far in helping to produce the Perfect Paper.

We hold no brief for nationalism in matters of science—*la chimie est une science française* is a

historic phrase which may well give pause to the enthusiastic nationalist—but, as a matter of plain fact, nuclear physics owes so much to Rutherford, and our knowledge of the solid state to Bragg, that the holding in London of an international conference dealing with these topics was most appropriate, and the conference was specially fortunate in that the discussions on the principal topics were opened by masterly surveys of the problems of nuclear physics and of the solid state contributed by these protagonists—surveys which form the opening addresses of the principal volumes of the conference report, and which serve admirably as introductions to the more specialised topics of the discussion.

It is quite impossible to give a detailed analysis of the contents of the volumes, and we must content ourselves with a brief catalogue of headings. The volume on nuclear physics contains sections dealing with general quantum theory, natural β-decay, artificial radioactivity, disintegration and synthesis of nuclei and elementary particles, and cosmic radiation. That on the solid state is divided into chapters which discuss the structure of molecules and of the ideal lattice, the deviations of real crystals from the ideal lattice structure, and plasticity and strain hardening in crystals. The papers are printed *in extenso*, the discussions are very fully reported, and one need say no more on the contents than that they represent the latest views on the subjects concerned, presented by physicists of international reputation.

The third volume of the report of the Conference—that dealing with symbols, units and nomenclature—may seem rather unexciting in comparison with its fellow volumes, but its subject matter is important, is thoroughly interesting, and presents a few intriguing problems for the physicist of philosophic mind. It is, for example, a little disturbing to the writer of elementary textbooks to be confronted with the statement that "complete agreement as to the definitions of B and H has not yet been reached".

(2) We turn now to the consideration of the first volume of what will, we trust, be a long and successful series of reports which will play an important part in the advancement of physical science. The report on the progress of physics issued by the Physical Society deals mainly with the events of the year 1933, although the fact that most of the surveys are the first of a series has allowed the contributors some measure of latitude, and earlier work, leading up to that of the year with which the reports are mainly concerned, is treated with the appropriate amount of detail. The reports contained in the volume are divided into two main groups—a set of reports which deal with general physics, sound, spectroscopy, optics, heat, X-rays, atomic physics and electrical and magnetic measurements. These titles are more or less permanent, so that reports under these heads will recur annually. The second group consists of a series of reports dealing with matters of topical interest, and the titles of these reports will vary from year to year. Under this head the present volume contains reports dealing with spiral nebulæ, Burgers' theory of turbulence, and electrical phenomena at extremely low temperatures. It has been found desirable to break up some of the reports into sub-sections contributed by specialists under the general direction of an editor. Thus, spectroscopy is split into twelve, X-rays into eight, and optics into five subsections.

It is not easy to settle the scope of such reports. What may be stated at once and decisively is that the reports are *not* mere expansions of *Science Abstracts*. They are popular in that they endeavour to present a review of different departments of physical science which shall be useful to the trained physicist who is not a specialist in the department under review—who wants to know, in fact, what is happening in branches of physics other than his own. They are specialised in that they offer full, critical and detailed accounts of the latest happenings in any particular branch of the subject, accompanied by very complete bibliographical details. An attempt to combine these two outlooks may seem to be courting failure, but it must be confessed that the reports combine these aspects very happily.

It is impossible, again, to deal with this report in detail, and it were invidious to particularise. But we cannot close this review without special mention of the brilliant contributions made by Prof. E. N. da C. Andrade, who deals with the physics of the atom, and by Prof. J. C. McLennan, who writes on electrical phenomena at very low temperatures.

No advanced worker in physical science can afford to neglect this report. The subject matter is extensive and important, the printing and production leave nothing to be desired, the price is low. If succeeding volumes preserve the high standard of the first volume, the success of the venture is assured.

British Scientists of the Nineteenth Century
By J. G. Crowther. Pp. xii+332+12 plates. (London: Kegan Paul and Co., Ltd., 1935.) 12*s*. 6*d*. net.

COMPARATIVELY few historians of science have as yet recognised the powerful influence which social forces have had on the development of science, and it is characteristic of this book that Mr. Crowther sets out to overthrow the idea that scientific knowledge

originates entirely in minds completely detached from mundane affairs and concerned solely with the pursuit of truth for its own sake. He offers instead a picture of the lives of Davy, Faraday, Joule, Kelvin and Clerk Maxwell, in which we see how their characters were moulded by early upbringing, and the way in which their work was determined by various social and industrial influences. In revealing the extent to which other incentives besides the desire to contribute to the advancement of knowledge affected their careers, Mr. Crowther gives us a highly stimulating series of studies which appear appropriately at a moment when scientific workers are considering much more seriously both the social consequences of their work and the social factors which determine its extent or direction.

The selection of four physicists and a physical chemist as the most representative men of science of the century is defended on grounds that there were few outstanding figures in the fields of medicine, geology, botany and zoology during the period, in itself an example of the way in which the sciences which promised the greatest direct contribution to the prosperity of industry were the most richly endowed, while the biological, sociological and psychological sciences, which could offer no such immediate return, were much less generously encouraged. Although the author's opposition to capitalism tends to obtrude at times, it scarcely detracts from the fascination and suggestiveness of what is not merely biography but also to some extent a study of the effect of social conditions on the general development of science during the period.

R. B.

A Text-Book of Physical Chemistry

Vol. 2: Principles involved in Chemical Reactivity. By Dr. J. Newton Friend. Pp. xii+483+3 plates. (London: Charles Griffin and Co., Ltd., 1935.) 24*s*. net.

THERE is a pleasantly classical flavour about the second volume of Dr. Friend's treatise. Most of our old acquaintances are there, and though the ultra-modern physicist, "trained in an atmosphere of rigid economy of mechanical concepts" (an economy, Heaven help him, which leads on occasion to glib outpourings concerning the uncertainty principle, and a discreet silence concerning the mode of action of a locking-nut), may find overmuch of ancientry in the exposition, the student who has attacked the fundamentals of physical chemistry with the aid of Dr. Friend's two volumes will not have a great deal to unlearn. The principal topics to which the ten chapters of the second volume are devoted are thermochemistry, chemical equilibrium, reaction velocity and chemical change in homogeneous systems, combustion in gases, the phase rule, catalysis, electrochemistry, the structure of the atom and of the molecule, and chemical thermodynamics.

The treatment is throughout clear, concise and elementary. Broadly speaking, the treatise will serve to lay the foundations for an advanced honours course.

A. F.

The Biology of Bacteria: an Introduction to General Microbiology

By Prof. Arthur T. Henrici. Pp. xi+472. (Boston, New York and Chicago: D. C. Heath and Co.; London: George G. Harrap and Co., Ltd., 1934.) 12*s*. 6*d*. net.

THIS book, as explained in the preface, is intended as an introduction to microbiology in its scientific aspects as distinct from its practical applications in hygiene, agriculture and industry. The author, indeed, considers that the lower unicellular micro-organisms present problems sufficiently important to warrant microbiology being considered as a separate branch of biology, distinct from either botany or zoology. At the same time, when dealing with individual organisms, their rôle in the causation of disease, or their importance in agriculture and industry, are adequately described, and immunity, antibodies and antisera, agglutination and the like, are all considered.

After a brief history of bacteriology and some details respecting the microscope, the microbic life of the Protozoa, Algæ, Fungi, Bacteria and other unicellular groups is considered. In these chapters the structure, nutrition, reproduction and other functions of each group are surveyed. The 'ultra-microbes', the finer structure of Bacteria, and the subjects of heredity, variation and metabolism in this group form the subject of several chapters. In this connexion, the author has definite views on the meaning and importance of Gram-staining, holding that the Gram-positive species form a homogeneous group distinct from the Gram-negative species, and bringing them in relation to the Fungi. In the many instances where alternative hypotheses are possible, for example, as regards the nature of 'bacteriophage', these are clearly stated.

The book is well produced and illustrated, and gives an excellent account of the biology of the Bacteria.

R. T. H.

Zur Erforschung des Weltalls: acht Vorträge über Probleme der Astronomie und Astrophysik

Von P. ten Bruggencate, E. F. Freundlich, W. Grotrian, H. Kienle, A. Kopff. Herausgegeben von W. Grotrian und A. Kopff. Pp. x+286. (Berlin: Julius Springer, 1934.) 19.80 gold marks.

THIS is not in the strict sense a popular book. It is, however, an account by a group of well qualified German astronomers of some of the recent researches and outstanding problems in their subject, written for readers with a reasonable knowledge of mathematics and physics. The authors' names are a sufficient guarantee of the quality of the volume. The subjects discussed—methods of astrometry, the physical condition of the stars, their inner constitution and evolution, the structure of the stellar system, the sun—reflect a sound choice from the whole range of astronomical knowledge. The volume arose from a series of eight lectures given to a circle of engineers at Charlottenburg in 1933. It is freely and well illustrated and attractively set out. It fills what is probably a real need in astronomical literature.

Temperature Changes in the Higher Atmosphere

By Prof. E. V. Appleton, F.R.S.

UNTIL some years ago, it was generally thought that the temperature of the stratosphere was practically uniform, and of the order of 220° K. A radical change in such notions was first effected by Lindemann and Dobson who, in 1922, from their study of meteor tracks, showed that the temperature at levels above 60 km. was even higher than that at ground-level. Their conclusions have been adequately confirmed recently in experiments on the anomalous propagation of acoustic waves, on the vertical distribution of ozone with height and, to some extent, by direct temperature measurements in high balloon ascents. There is, then, trustworthy evidence that solar radiation does not pass through the middle part of the atmosphere without warming it, so that we are led to examine, in this connexion, the evidence relating to still higher atmospheric levels, where such heating might be expected to be especially pronounced, since the solar radiation is there most intense and the thermal capacity of the transmission medium least.

Within the last year or so, the study of the diurnal and seasonal changes in upper-atmospheric phenomena by radio methods has indicated that surprisingly high temperatures are attained at great heights (200–400 km.) and that these temperatures vary in a most pronounced manner. These conclusions have been reached by comparing the observed diurnal and seasonal variations of ionisation with those expected according to a simple theory of photo-ionisation by solar radiation. It is now well known that there are two main regions of ionisation in the upper atmosphere, the lower of which (Region *E*) is the Kennelly-Heaviside layer. Now the maximum ionisation content of the Kennelly-Heaviside layer varies with the hour of the day and with the season of the year much as simple theory predicts. For example, the ratio of summer to winter noon maximum ionisation depends on the zenith distances attained by the sun at noon in summer and in winter. For the latitude of Great Britain, a simple calculation shows that the theoretical value of this ratio should be 1·84, and observations made at the Slough Radio Research Station of the National Physical Laboratory and at the Halley Stewart Laboratory, Hampstead, London, yield an experimental value agreeing very closely with this.

This agreement indicates that, at the level of the Kennelly-Heaviside layer (100 km.), there is little change of air density or temperature throughout the year. But above the Kennelly-Heaviside layer there is a much more intensely ionised region, Region *F*, and corresponding measurements in this case provide no such agreement with theory. For example, the critical penetration wireless frequency, by way of which the maximum ionisation is measured, is found to be actually less on a summer noon than on a winter noon, indicating that, in contrast to the results obtained for Region *E*, the maximum ionisation in Region *F* is less on a summer noon than on a winter noon. This result appeared at first sight so startling that some workers concluded that the critical frequency method of measuring atmospheric ionisation was untrustworthy, and that observations made by it could not be accepted. But further work carried out in Great Britain indicates that the method of measurement is trustworthy, and we must face the consequences of these unexpected results. Discrepancies between theory and experiment are always interesting, for from the discrepancy we can often measure the magnitude of the perturbing factor.

Fortunately, in this case, an explanation is to hand. The theory which indicates that summer noon ionisation should be nearly twice that on a winter noon is founded on the assumption that the atmospheric distribution of molecular density with height is constant throughout the year. It is not difficult to show that the abnormally low value of summer noon ionisation density can only be the result of a reduced summer air density at the level in question, otherwise we should have to assume that the solar ionising rays differed in quality from summer to winter. Such a reduced air density can again only be the result of an increased temperature. Putting these ideas into quantitative form, we find that the molecular temperature must be three to nine times as high on a summer noon as on a winter noon, and that the absolute temperature at a level of 300 km. must be at least 1,200° K. on a summer day.

An equally interesting result emerges from the interpretation of the corresponding nocturnal ionisation measurements. When the sun sets, it is found that the rate of decay of Region *F* ionisation, which has been proceeding in accordance with the decreasing zenith distance of the sun, is quite suddenly checked on a winter night. It appears as if there were brought into action a

new source of ionisation, but this is not so. The effect is due to the shrinkage of the outer layer of the atmosphere due to cooling, which brings about a concentration of both molecules and electrons. (Note that wireless methods measure not total ionisation but maximum ionisation per unit volume.) It is found that the concentration of electrons due to upper-atmospheric shrinkage can more than offset the dilution due to recombination processes, and an actual maximum of ionisation content is attained in winter, shortly after midnight. In midsummer no such marked cooling process takes place (for the sun never sets at heights of above 250 km.) and the ionisation (apart from occasional increases which are probably due to a nocturnal ionising agency) is generally found to decay steadily.

The theory of marked temperature changes also suggests an explanation for the curious alteration of structure which Region F undergoes on a summer day. It was shown in 1933 that there is found in our latitudes a subdivision of Region F during daylight in summer. When distinction is necessary we refer to the lower part, which forms a kind of 'step' on the upper part, as Region F_1, while the upper stratum is referred to as Region F_2. Since Region F_1 is found not to exhibit marked temperature changes, it is quite possible that the subdivision is partly, if not wholly, the result of the difference of the temperatures at the two levels, Region F_1 being at the lower temperature and Region F_2 at the higher temperature. According to this view, Region F_2 is, as it were, part of the main Region F forced upwards by expansion. At night, when the atmosphere shrinks, the two regions tend to merge into a single simple region. It is thus not improbable that differences of temperature in the atmosphere, as well as differences in molecular constitution, play a part in causing the composite structure of the ionosphere.

It might appear that these extraordinarily large changes of temperature at high atmospheric levels could not possibly have any influence on wireless communications, but such is not the case. Due to the expansion of the upper atmosphere on a summer day, the maximum electronic density, which determines the shortest wave-length usable in round-the-world communication, is abnormally low, and we are therefore unable to use a valuable range of short wave-length channels. Fortunately, however, Nature provides us to some extent with a form of compensation, for it is found that in summer there is very frequently produced a curious highly-reflecting stratum about the level of Region E, which provides abnormally favourable transmission conditions for short waves. But such conditions do not occur daily and so cannot be relied on wholly to remove the unfavourable conditions brought about by the solar heating and expansion of Region F_2 on a summer day.

Implementiferous Gravels of the Vaal River at Riverview Estates

By Prof. C. van Riet Lowe, Bureau of Archæology, Dept. of the Interior, Johannesburg

TOWARDS the end of April last, Mr. F. W. Webber, chairman of Carrig Diamonds, Ltd., very generously presented a collection of stone implements and a variety of deeply mineralised faunal remains to the Bureau of Archæology recently established at the University of the Witwatersrand. These had been recovered from diamondiferous gravels on the property of Carrig Diamonds, Ltd., at Riverview Estates on the left bank of the Vaal River immediately opposite Windsorton (lat. 28° 20′ S., long. 24° 44′ E.) shown on the accompanying sketch plan (Fig. 1). As similar remains were still being recovered, I immediately requested Dr. S. H. Haughton, director of the Geological Survey of the Union of South Africa, to accompany me to the site with the object of a detailed investigation. Mr. F. W. Webber had kindly offered to accompany and guide us, and an examination of the area was accordingly carried out during the second week in May.

The ancient gravels were found to be extremely rich in implements and faunal remains, and the occurrence, as a whole, unusually interesting and embracing. Until we are in a position to publish detailed reports, however, the following occurrences are noteworthy.

1. The 60 ft. terrace, shown as Site No. 5 on the accompanying 'composite sections' drawing (Fig. 2), comprises a thin layer of gravels that caps the old peneplain some sixty feet above the present flood plain. Inclement weather precluded the possibility of a thorough examination, but in the time at our disposal we were unable to find even traces of the manufacture of stone implements.

2 (*a*). In the lower terrace, actually an old river gravel, marked 'G' on sections 1, 2, 3 and 4 in Fig. 2, we recovered a few heavily rolled Lower Stellenbosch (Chelles plus Clacton type) tools and a great abundance of rolled and unrolled Upper

Stellenbosch (Acheul plus Proto-Levallois type) tools and the completely mineralised remains of a variety of extinct animals which Dr. Haughton will describe when he publishes his geological and other data.

In this Upper Stellenbosch congeries we have further definite proof, were this indeed required, that the so-called Victoria West industry merely represents the factory-site debris of the Upper Stellenbosch culture[1], for in addition to very many fine hand-axes and cleavers worked on flakes, we found numbers of detaching hammers and typical Victoria West cores from which the flakes (large and small) used for these axes and cleavers were struck. Several cores are normal in size, that is,

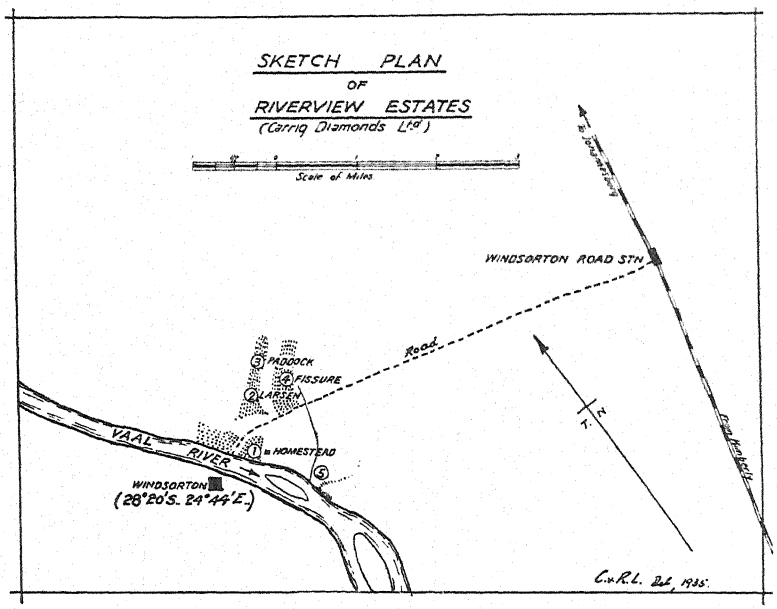

FIG. 1.

up to about 9 in. in length, but others are more than 15 in. long by 8–10 in. broad and deep and up to 150 lb. in weight. Twelve-inch flakes were struck from these great cores—cores frequently trimmed in typical Victoria West fashion *before* the flakes were removed. The materials preferred comprise varieties of Ventersdorp lava and quartzites, the weathering properties of which are entirely different from those of Victoria West (Karroo) dolerites, where insolation is common. No doubt whatever can be cast upon the purposeful shaping of these cores as a preliminary to the removal of the flakes that were ultimately trimmed into hand-axes and cleavers that vary from about three to ten inches in length.

It is this technique that I have in the past referred to as Proto-Levalloisian[2]—a highly specialised technique that enabled the manufacturers to produce axes or cleavers at will—a technique apparently unknown out of South Africa, though, I must confess, I suspect its occurrence in southern India. Once this special technique is understood and it is realised what a great proportion of the tools are cleavers, the necessity for breaking away from the use of such terms as 'Chellean' and 'Acheulean' will be more readily appreciated.

(*b*) The occurrence of rolled and unrolled implements and factory site debris at all levels in the gravels establishes the fact that the makers of Upper Stellenbosch tools occupied the valley before and during the deposition of these gravels. Dr. Haughton is equally satisfied that the animals, the fossil remains of which we recovered, also occupied the valley during this period. The animal remains include horse, buffalo, antelope, at least one large carnivore, hippopotamus, etc.

3 (*a*). Overlying these ancient gravels is a layer of silt and calcareous tufa that varies appreciably in texture and depth. But for a single *biface* (not seen) reported by Mr. Larsen as having been found at a depth of 15 ft. below the natural ground surface at Site No. 2, the silts and tufas of Sites Nos. 2, 3 and 4 appear to be sterile. At Site No. 1, marked 'Homestead' in Fig. 2, the silt is a loose sandy soil that is subject to movement by wind and rain. At Site No. 2 ('Larsen'), the silt is well consolidated and toward the surface passes into a calcareous tufa. The fact that 35-ft. high walls remain vertical without supports is illustrative of the high degree of consolidation. Except for three feet immediately over the gravels, penetration can only be effected by means of picks. This is largely, if not wholly, due to the formation of calcareous tufa in the deposit. Larsen's Site (No. 2) is probably the most interesting.

The diamondiferous gravels occur 35 ft. below the present ground surface and extend laterally over several acres, at a distance of 1–1½ miles from the river. They are reached by vertical shafts through the calcareous tufa and silt, and are 'worked' by means of tunnels. Shafts are sunk at fairly close intervals and intercommunication is maintained until the gravels are 'worked out' or a collapse occurs. We were able to walk about in these underground corridors, and with the aid of torches, to examine the undisturbed gravels in comfort.

At Site No. 3 ('Paddock'), situated about a

quarter of a mile from Site No. 2, the excavation is a huge open hole the walls of which are vertical and the silt therefore obviously also well consolidated. Immediately above the gravels the silt is a fine, clean sand—water-worn and false-bedded. Higher up the calcareous tufa occurs again. All these walls, both in shafts and open excavations, appeared to be sterile.

Between Sites Nos. 3 and 4 there occurs a barren patch, and at Site No. 4 the gravels and silt alternate as shown.

(*b*) At Site No. 1 ('Homestead'), the silt and later loose sand that cover the surface yielded a complete assemblage of Lower Fauresmith (mainly Micoque and Old Levallois type) tools. As this is only the second discovery of Stellenbosch-Fauresmith stratification, it is most important. The first was recorded six years ago[3]. Small and well and neatly trimmed hand-axes, two cleavers, a scraper, several Levallois type flakes, fabricators, etc., were recovered—a good assemblage in a stratum very much more recent than the underlying gravels with their Upper Stellenbosch remains. The tools are almost exclusively of indurated shale (lydianite), though lava and quartzite appear also.

4. Lying entirely on the natural ground surface or just below the superficial shifting sands at Site No. 1 and at the foot of the scarp at Site No. 5, I collected deeply weathered Middle Stone Age (Late Levallois cum Moustier type) and slightly weathered remains of the Middle Smithfield (Capsio-Aurignacian type) culture.

The Middle Stone Age material is recognisable, but somewhat nondescript—mainly unworked flakes and a few small and inferior cores—but the Later Stone Age (Smithfield culture) comprises the usual variety and number of duckbill end-scrapers, side- and thumbnail scrapers, one bored-stone, one grindstone and one well-worked elongated phallus-like cylindrical artefact, truncated at one end and nosed at the other, 8¼ in. long with a maximum diameter of 2¼ in.

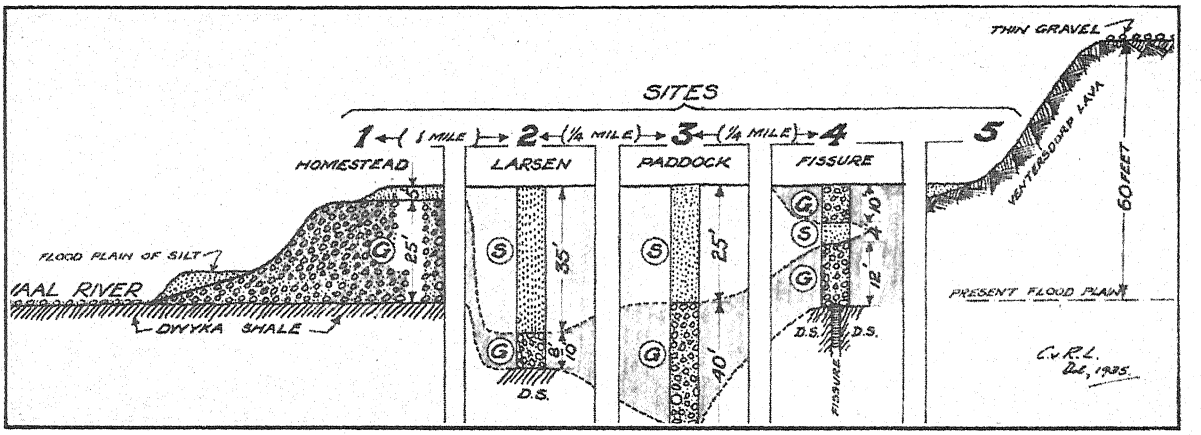

FIG. 2. Composite (diagrammatic) sections of the left bank of the Vaal River at Riverview Estates

SUMMARY OF STRATIFICATION

1. Slightly weathered Middle Smithfield (Capsio-Aurignacian type) and much weathered Middle Stone Age (Late Levallois cum Moustier types) on surface at Site No. 1 and at foot of scarp at Site No. 5.

2. Deeply incrusted Lower Fauresmith (La Micoque cum Old Levallois types) in silt and loose sand capping gravels at Site No. 1.

3. Rolled and unrolled Upper Stellenbosch (Acheul plus Proto-Levallois type) implements and factory-site debris (Victoria West cores ≡ Proto-Levallois technique) and heavily rolled Lower Stellenbosch (Chelles plus Clacton-like flakes) throughout gravels at Sites Nos. 1, 2 and 3.

4. Three heavily rolled Clacton-like flakes of the Lower Stellenbosch recovered from mounds of 'worked' gravels removed from Site No. 4 after excavation. Horizon unknown.

In submitting this preliminary report, I do so with the hope that the larger and more detailed publications will not be long delayed. Dr. Haughton has very kindly undertaken to deal with the geology, palæontology and climatology of the area and the periods affected, and in doing so will, I have no doubt, add weight to my oft-expressed opinion that such closely related major problems as these that do not fall within the strictly specialised field of the prehistoric archæologist *qua* archæologist, should be left entirely to the other specialist or specialists concerned. It is only with the fullest support of the pleistocene geologist that

the archæologist can hope to solve the problems of early human cultures not only in Africa but also elsewhere.

In conclusion, I would like to express my great indebtedness to Mr. Webber and to Messrs. R. W. Hardy and Larsen, who put themselves, their discoveries and vast knowledge of the 'diggings' entirely at our disposal. To Mr. and Mrs. Hardy we are deeply indebted for hospitality during a particularly inclement week.

Tercentenary of Robert Hooke, 1635-1703

OF all the scientific worthies of the seventeenth century, none will be remembered longer than Robert Hooke, whose views and activities influenced the progress of scientific thought and practical physics in an incalculable degree. Somewhat younger than Boyle, Wilkins, Wren, Mariotte, von Guericke and Huygens, but the senior of Flamsteed, Newton, Leibniz and Halley, he belonged to an age in which, in the words of Macaulay, "it was almost necessary to the character of a fine gentleman to have something to say about air-pumps and telescopes". Born when James I was king, Hooke was a schoolboy in Westminster when Charles I was beheaded, a scholar at Oxford when Cromwell was Protector and an assistant to Boyle at the time of the Restoration. As curator, and sometime secretary, he faithfully served the Royal Society during practically all the reigns of Charles II, James II and William and Mary, and died a year after Anne ascended the throne. Affairs of State and Church, however, made little difference to Hooke, and in the main his life was taken up with writing, lecturing and experiment. In the records of the first forty years of the Royal Society, no name is more frequently met with than his, and in his various capacities of curator, Gresham professor of geometry and Cutlerian lecturer on mechanics, he probably delivered more scientific discourses and made more experiments than any other man of his day. His influence was felt both at home and abroad, and the story of his life belongs to the history of our race in the same way as those of his contemporaries Dryden, Locke, Evelyn and Pepys.

Hooke was the son of the Rev. John Hooke, a curate of Freshwater, Isle of Wight, where he was born on July 18, 1635. He was a somewhat delicate child, and was kept at home until his father's death in 1648, when, after a short time with Lely, the portrait painter, he entered Westminster School and thus came under the famous Dr. Busby. Studious and inventive far beyond the average, at eighteen years of age he became a chorister and servitor at Christ Church, Oxford, and during the next eight or nine years gained the friendship of Wilkins, Ward, Willis, Petty, Boyle and other men of science, whose meetings at Oxford had much to do with the inauguration of the Royal Society in 1660.

The turning point in Hooke's career came in 1662 when, as the Journal Book of the Royal Society records, "Nov. 12, 1662. Sir Robert Moray proposed Mr. Hooke as a curator of experiments to the Society . . . and that Mr. Hooke should come and sit amongst them, and both bring in every day of the meeting three or four experiments of his own, and take care of such others, as should be mentioned to him by the Society". His connexion with the Society was strengthened next year by his election as a fellow, and in 1665 by his appointment to the chair of geometry in Gresham College, where the Society at that time met, and where Hooke lived for the rest of his life. He had already in 1664 been appointed to the lectureship founded by a city merchant, Sir John Cutler, Bt., and thus at thirty years of age Hooke found himself established in surroundings which must have appeared to him as congenial as those at the Royal Institution did to Faraday a century and a half later.

Of Hooke's versatility, originality and inventiveness ample evidence is to be found in his writings, but new and valuable information as to his activities in early middle life is contained in the "Diary", the recent publication of which we owe to Mr. H. W. Robinson and Mr. W. Adams. This diary covers the years 1672–80, when, in addition to his other appointments, Hooke was one of the surveyors of the City of London. The biographical index to the diary contains several hundreds of names, among them most of his scientific contemporaries.

Hooke himself was at once a physicist, an astronomer, an inventor, a mechanician and an architect. To horologists he is known for his application of the balance spring and the invention of the anchor escapement; by engineers he is remembered for his universal joint and his views

on elasticity; as an instrument maker he made improvements in thermometers, barometers, air pumps and microscopes, and he devised sounding apparatus for sailors and calculating machines. He was the first to describe the cellular structure of plants and the first to suggest the use that might be made of fossils in revealing the history of the earth. He had advanced views on gravity, colours and light, respiration, combustion and the nature of heat. His "Micrographia", published when he was thirty years of age, was the first major treatise on the microscope and microscopy. His "Attempt to prove the motion of the Earth" was published in 1674; his "Description of Helioscopes" in 1676; his "Cometa" in 1679. Many of his lectures and writings, however, were only published after his death. They are all full of pregnant suggestions, and as Dr. Singer says: "No Englishman of science has outlined so many and so variously important discoveries".

It was the Great Fire of London in 1666 which led Hooke to become an architect. While the ruins of the city were still smouldering, he produced a plan for rebuilding it. Although his plan was approved by the Royal Society, it was not adopted; but on October 4, 1666, the City made him one of its surveyors. Henceforth much of his time was taken up in attending committees, superintending the rebuilding of houses and designing structures such as the Bethlehem Hospital, Moorfields, Montagu House, which stood on a site now covered by the British Museum, the Merchant Taylors' Hall, and numerous churches and private residences. It was from this work that he accumulated the large sum of money which he intended to bequeath for the purpose of erecting a library, repository and laboratory for the Royal Society, a project which, however, came to nothing owing to his failure to make a will.

"There is a peculiar fascination," said Lord Oxford, "in trying to pierce through the gloom which veils the life-history of some of the most famous of our race." In endeavouring to do this in the case of Hooke, the newly-published "Diary" will be of the greatest interest. Hitherto opinion has been largely influenced by the remark of his biographer, Richard Waller, who said that "his temper was melancholy, mistrustful and jealous, which more increased upon him with his years". Always somewhat of a valetudinarian, Hooke had his share of troubles, and the picture of him as a lonely old bachelor in his somewhat neglected apartments in Gresham's decaying mansion in Bishopsgate Street no doubt is a true one. But in the "Diary" he is seen as a man of forty, mixing freely with his fellows, meeting at many coffee-houses and taverns, discussing a hundred different matters. His friend John Aubrey, the antiquarian, writing about this time, said of him: "He is of middling stature, somewhat crooked, pale faced: and his face but little belowe, but his head is large; his eie is full and popping, and not quick; a grey eie. He has a delicate head of haire, browne, and of an excellent moist curle. He is and ever was very temperate and moderate in dyet, etc. As he is of prodigious inventive head so he is a person of great vertue and goodness."

There is, unfortunately, no portrait of Hooke. Neither is there any monument to him. He died in Gresham College on March 3, 1703, and a day or two later, in the presence of the fellows of the Royal Society, was carried across Bishopsgate Street to St. Helen's and there laid to rest in the chancel. The exact site of his grave is not known, but at the west end of the Nun's Choir of the church is a window of five lights to ten Worthies of St. Helen's, among the names of whom is that of Robert Hooke.

Obituary

Prof. Alice Werner, C.B.E.

WE regret to record the death, which took place at Welwyn Garden City on June 9 at the age of seventy-five years, of Prof. Alice Werner, emeritus professor of Swahili and Bantu languages in the University of London.

If the study of questions relating to the African in Great Britain has been determined largely by the influence of Mary Kingsley, the study of the Bantu languages and mentality as an academic subject owes no less to Prof. Werner. She was born at Trieste on June 26, 1859, and educated at Newnham College. An unusual gift for languages and an absorbing interest in certain aspects of the mentality of the less-sophisticated peoples drew her to Africa. From 1893 onward, she lived there for some time at first with the Scottish Mission at Blantyre in Nyasaland, and afterwards in South Africa, where she was deeply influenced during her study of the Zulu language and people by the Misses Colenso, the daughters of the famous Bishop of Natal, and laid the foundation for that sympathetic understanding of the Bantu peoples which was such an outstanding feature in her academic and literary work. A second visit to Africa took place in 1911, when she spent two years as Mary Ewart travelling scholar of

Newnham College in visiting various peoples in East Africa. On her return in 1913 she was made a research fellow of her college.

Miss Werner's most important services to African scholarship date from 1899, when she opened a school for the study of African languages in Westminster, which was afterwards transferred to King's College and recognised by the University of London, while Miss Werner became successively lecturer, reader and professor. On the opening of the School of Oriental Studies of the University of London in 1917 she was appointed lecturer in Swahili and Bantu, and the position these studies now hold in the School is due to her enthusiasm and untiring energy.

In 1930, Miss Werner became emeritus professor, after receiving the degree of D.Litt. in 1928. In 1931 she was awarded the Silver Medal of the African Society, of which she was a vice-president at the time of her death, and in the same year was made a C.B.E.

Miss Werner was the author of a number of works dealing with African languages and folklore, among the best-known being "African Mythology" (1926) and the scholarly and at the same time delightful "Myths and Legends of the Bantu" (1933), while "The Structure and Relationship of the African Languages" (1930) sums up the results of many years study of material gathered at first-hand as well as critical examination of the work of other scholars. Miss Werner was a constant contributor to the periodicals of learned societies and the reviews. She wrote with a light touch which was derived from a thorough mastery of a wide range of knowledge; and, if an exacting critic, she was ever kindly, and her criticism constructive.

News and Views

Cultural Succession in the South African Stone Age

A PRELIMINARY report by Prof. C. van Riet Lowe on a discovery of faunal remains and stone implements of early man in the diamondiferous gravels of the Vaal River (see p. 53) is the first account in any detail to reach Great Britain of a firmly established archæological succession in the early stone age cultures of South Africa, which, it is safe to predict, will be a standard of reference in future research. From the evidence of five sites on the Riverview Estates, a diagrammatic section of stratification has been constructed which shows a regular chronological succession of cultures in the Lower, Middle and Later Stone Ages from 'Chellean' to 'Capsio-Aurignacian'. Points of special significance emerging are the identification of the much discussed so-called Victoria West industry, with its gigantic stone cores, as the factory *débris* of the Upper Stellenbosch of Lower Palæolithic age; the occupation by man of the Vaal River Valley both during and after the deposition of the old river gravel—the full significance of this will appear on publication of the palæontological evidence; the confirmation of the chronological relation of Upper Stellenbosch and Fauresmith cultures, the latter being shown by stratigraphic evidence to be of much later age; and the local specialisation in South African cultures and technique, which renders inept the application of a West European terminology. While the author refrains from broader inference, pending the opinion of experts on geological, climatological and palæontological evidence in a report now in preparation, the conclusion is warranted that this discovery will have more than local significance, especially as a contribution to the study of the great hand-axe culture, characteristic of Africa, but of highly specialised technique in South Africa, and distributed from Great Britain to India and even beyond.

Presentation of the Albert Medal to Sir Robert Hadfield

H.R.H. THE DUKE OF CONNAUGHT, president of the Royal Society of Arts, presented the Society's Albert Medal for 1935 to Sir Robert Hadfield on July 8 "for his Researches in Metallurgy and his Services to the Steel Industry". In making the presentation the Duke of Connaught said: "It gives me very particular pleasure on this occasion to present the Albert Medal of the Royal Society of Arts, a very high honour, which was founded in memory of my father, to one who has been a personal friend and a charming next door neighbour of mine in the south of France for many years. Your labours in the application of scientific research to the great steel industry have contributed greatly to its progress. As far back as 1882, by the discovery of manganese steel, you opened a new chapter in the history of metallurgy, and this remarkable alloy, which has found many uses in engineering and in mining, has also stimulated research into the causes of its unique hardness, and into the structure of the alloys of iron. As an industrialist, you have given great encouragement to scientific research in metallurgy by your example, and you have consistently upheld the view that the future of industry in this country is closely bound up with the attention which it gives to research". Sir Robert Hadfield, in accepting the Medal, expressed his gratification at the honour conferred on him by the Society and reaffirmed his faith in the value of research. Speaking in particular of metallurgy, he referred to the fact that among the previous recipients of the Medal were Bessemer and Siemens. For himself, he said that during his life he had done his utmost along with many others "to raise metallurgy from an empirical art to a true and important branch of modern science. I venture to add without fear of contradiction that the study and practice of metallurgy is no longer empirical but

is now based on scientific and orderly lines and has become just as much a part of science as engineering, chemistry and physics".

Retirement of Prof. A. Morley Davies

AFTER more than thirty years' service as demonstrator, lecturer and assistant professor, Dr. Arthur Morley Davies will shortly retire from the Department of Geology of the Imperial College of Science and Technology and readership in the University of London. Opportunity was taken by his colleagues in the Department to make him a presentation on Tuesday, June 25. Prof. Boswell recalled that Prof. Davies joined the College fifty-one years ago, and became a member of a stimulating group of students which included such well-known figures as H. G. Wells, R. A. Gregory, A. T. Simmons, A. E. H. Tutton and A. V. Jennings. Tribute was paid to Prof. Davies for his long and devoted services to geology, to the College and to learned societies. The Royal Geographical Society conferred honorary fellowship on him, and the Geological Association honorary membership, as a mark of appreciation of his help and counsel during many years; and the Geological Society awarded him its Murchison Fund and, later, its Lyell Medal in recognition of his original work. Prof. Davies is the author of text-books of geography, local geology, palæontology and, recently, of two volumes on the Tertiary faunas, which will long remain a standard work of reference.

Memorial to Sir Patrick Geddes

THE Outlook Tower, standing on the Castle Hill, Edinburgh, was intended by the late Sir Patrick Geddes to express and exhibit stages of social development, using the history and geography of Edinburgh and Scotland as particular illustrations, and passing from them to the British Empire, the United States of America, Europe, and the world as a whole. The Tower was founded by him in 1892 as a type museum of geography, history and sociology and as a centre of civic and regional study; and it will always be associated with his name. There could be no more appropriate means of commemorating Sir Patrick Geddes' work and influence than by establishing the Outlook Tower upon a permanent basis, and thus enable it further to be developed as an active centre for the dissemination of his ideas. With this end in view, a memorial, signed by a number of his friends and admirers, has been circulated, inviting contributions and asking also for the loan of any original letters or personal reminiscences, which with a considerable body of material already collected will be classified and edited so as to be available to students of civics and sociology. As Geddes was the apostle of town and regional planning, and devoted his life to promote intelligent and stimulating relationships between man and his environment, we hope that the response to the appeal now made will be ready and generous. Contributions should be sent to Sir Thomas B. Whitson, 21 Rutland Street, Edinburgh, and letters or other personal communications bearing upon Sir Patrick Geddes' life and work to the honorary secretary, Outlook Tower, Castlehill, Edinburgh.

Gas-Storage of Fruit

FIVE coolers, specially made to complete the equipment of the experimental refrigerated chambers at the Ditton Laboratory of the Department of Scientific and Industrial Research, were presented to the Laboratory on July 5. Three of the coolers were given by Mr. S. W. Mount, of Patricksbourne, Canterbury, on behalf of a number of British fruit-growers who are owners of gas-stores; the other two by Lord Dudley Gordon on behalf of Messrs. J. and E. Hall, Ltd., refrigerating engineers of Dartford, by whom the coolers were designed and made. Sir Frank Smith, Secretary of the Department of Scientific and Industrial Research, in accepting the gift on behalf of the Department, said that it indicated the confidence of those concerned in the fruit-growing industry in the work of the Department.

IN the course of his remarks Sir Frank Smith said that English apples do not do so well in cold storage as those from some other parts of the world; they are liable to rapid wastage on removal from store as the direct result of exposure to the low temperature. Fortunately, the Department has been able to find a solution of this difficulty, namely, 'gas-storage'. At a temperature of 41° F., with the oxygen in the atmosphere reduced to 10 per cent, and with the carbon dioxide raised proportionally to 10 per cent—a result which can be simply achieved by controlled ventilation in a gas-tight store—the Bramley's Seedling can be kept in first-rate condition for so long as twelve months. The first commercial gas-store in Great Britain was built by Mr. Mount in 1929; to-day there are some forty gas-stores in operation with a total capacity of about 400,000 bushels. Gas-storage as a method of preserving fresh fruit is only in its infancy. During the 1934–35 season, home-grown pears, of the variety Conference, were kept in gas-storage at the Ditton Laboratory for some months, with highly promising results. The Laboratory has also carried out preliminary experiments on the gas-storage of tomatoes, and again the results have been sufficiently promising to warrant development.

Conference on Folk-Dancing

A CONFERENCE on folk-dancing, which is being held in London on July 15–20 in connexion with an International Folk-Dance Festival, will afford an exceptionally favourable opportunity for the comparative study of this survival of European folk art and ritual. Students from all parts of Europe, it is stated in a preliminary announcement by a correspondent of *The Times* in the issue of July 6, will be present, and will discuss selected and especially significant dances still found among the peasantry of the remoter parts of Europe. These will be illustrated in many instances by dancers of the country of origin, who are attending the conference

specially for the purpose. Thus Roumania will be represented by the seasonal hobby-horse dance performed by the Cališari with their heavy bells. The dance and its numerous seasonal parallels in other parts of Europe will be demonstrated and discussed by Prof. Vula. A Bulgarian theme, the 'spring maiden' of folk dance and song, will be analysed by Mme. Raina Katzarova, of the Ethnographical Museum, Sophia, who will illustrate her argument with movements by Bulgarian dancers. The interesting form of the sword dance found in Piedmont, with its singular combination with the maypole ritual and its resemblances in detail to the sword dance of Britain, will also be shown and afford an opportunity for comparison with a presentation of the Austrian sword dance, which has given evidence for an alternative explanation of the dance to that generally accepted. Britain, the Netherlands, France and Norway are among other countries providing material for discussion. The international folk-dance festivals which have been held in London in recent years have provided much interesting material for consideration, but on this occasion the conjunction of a conference dealing with study of the rituals, of which the dances preserve the evidence, should do much to advance the scientific study of this important department of primitive religion. The Conference will meet at the Cecil Sharp House, Regent's Park, London, N.W.1.

North East Coast Institution of Engineers and Shipbuilders

THE North East Coast Institution of Engineers and Shipbuilders will celebrate its jubilee on July 16–19 at Newcastle-on-Tyne. The Institution held its inaugural meeting on November 28, 1884, and from then until the present time has been one of the most active bodies concerned with the advancement of the sciences of engineering and shipbuilding not only in Great Britain, but also throughout the world. Representatives will attend the meeting from the leading British kindred societies and allied bodies, and also from France, Germany, Holland, Italy, Japan and the United States. The papers to be presented at the meeting will deal with the history of engineering during the past fifty years in the following sections: liners, cargo ships and tankers, coasters, marine turbines, reciprocating steam engines, marine boilers, marine heavy-oil engines, and recent progress in electrical and general engineering. Dr. John T. Batey will preside at the meetings. A pleasurable feature will be the presentation of acknowledgments to founder members. Notable among these are Sir George B. Hunter, Mr. J. Denham Christie, Prof. R. L. Weighton and Mr. W. G. Spence (the initiator and first honorary secretary of the Institution). The honorary fellowship of the Institution will be conferred upon the following: Mr. George Stephen Baker, superintendent of the William Froude Laboratory; Vice-Admiral Sir Harold A. Brown, engineer-in-chief of the Fleet; Sir Cecil Algernon Cochrane, chairman of Armstrong College Council, 1923–35; and Sir Arthur William Johns, director of naval construction.

Ultra-Violet Transmitting Glass

SPECIMENS of ultra-violet transmitting plate glass produced by Messrs. Pilkington Brothers Ltd., of St. Helens, Lancashire, show a region of high transmission in the region near 3650 A., with an almost complete opacity to the visible spectrum except in the extreme violet, where the transmission is, however, said to be only about 1 per cent. Tested with a powerful spark source and a monochromator, the claims of the makers were found to be justified. The transmission in the ultra-violet was comparable with that of an 'ultra-violet' glass from another source, the cadmium line near 3610 A. being freely transmitted; but whereas Messrs. Pilkington's new glass showed no transmission in the visible region when tested with a pocket spectroscope, the other glass showed a marked transmission band in the red. The glass can be manufactured in large sizes; specimens have been submitted of thickness 8 mm. and 11 mm. respectively. In view of the increasing importance of fluorescence tests, and other applications of ultra-violet radiation, numerous uses should be found for it, since its opacity to visible radiations should facilitate the distinction between genuine fluorescence and effects of reflected light. It may be worth noting that in very thin layers this new glass is of a blue-green colour. A prism of small angle ground to a very thin edge should make a very pretty example of dichromatism.

Scent and the Weather

HITHERTO, success in hunting has depended largely on popular omens of hunting conditions and on the practical experience of Masters of Hounds. The relation of scent and the weather formed the subject of a recent scientific study (see NATURE, April 14, 1934, p. 548). Now a meteorological officer of the Royal Air Force (R. G. Veryard) has supplied information enabling the Master to arrange place and time of meet to fit in with the best scenting conditions. In a pamphlet issued by the Masters of Foxhounds Association of India (Lieut.-Col. C. J. R. Turner, 47th Sikhs, Chaman, Baluchistan. 3 rupees), although specially written for the Peshawar Vale Hunt, he discusses many points which are of more than local interest. An inversion, or low lapse-rate of temperature, involving a restriction of the upward motion of eddies, is mainly favourable for good scenting conditions. The author does not agree with Mr. Budgett's view that for scenting conditions to be good the ground must always be warmer than the air, because a superadiabatic lapse-rate near the ground causes atmospheric turbulence which dissipates even scents which were quite strong initially. The number of good and bad scenting days are approximately equal during a calm, but, with a moderate wind, up to 3 on the Beaufort scale, the rate of evaporation is increased and scent may be good. If the air is less than 30 per cent saturated, scenting conditions are likely to be poor. Scent is more likely to be good if the soil is moist than if it is dry. The best hunting conditions in Peshawar obtained when the air temperature registered between 40° and 65° F.,

that is, in the morning. A general survey of meteorological conditions over the hunting season undoubtedly resulted in better sport, scenting conditions being predicted with fair accuracy for particular days. It is suggested that, from a study of the meteorological elements in relation to scent, a Master of Hounds will be able to frame suitable questions, the replies to which will give him a good idea how he can benefit by the information.

Micro-Climatology

A NEW quarterly journal entitled *Bioklimatische Beiblätter der Meteorologischen Zeitschrift* made its appearance last year. It is a joint production of the German and Austrian Meteorological Societies, and is edited by Drs. W. Schmidt of Vienna and F. Linke of Frankfort a. M. A specimen number (Band 1, Heft 3) has been received from Dr. Schmidt. It sets out to deal with observations made in such a way as to represent the climates actually experienced by various living organisms; in other words, to portray the so-called micro-climates. Micro-climatology is a comparatively new subject, and one which has a scope that is great in proportion as there are innumerable problems of a biological nature to which it has some application. Among the papers in this specimen copy is one by F. Steinhauser which is a good example of micro-climatology: it is a study of the special temperature conditions which the dwellers in large towns experience out of doors, conditions which are different from those prevailing in neighbouring open country, and which are of biological importance to the people concerned. Another paper, by W. Kühnelt, deals with the general significance of climate for the animal kingdom. These are both largely surveys of work done by those engaged on those special questions; in another, by Dr. Linke, one of the editors, a brief survey is given of the pioneer work of W. F. Tyler on the psychological effects of various degrees of relative humidity combined with high temperature, founded on studies made in Shanghai, from which Tyler drew lines of equal discomfort termed 'hythers' on a temperature and relative humidity diagram.

Chemical Industry in the United States

THREE hundred years ago, there was established in Boston "a strange combination of druggist's shop, metallurgist's workroom, chemist's laboratory, and alchemist's den" which may fairly claim to have given birth to the American chemical industry. It was the enterprise of John Winthrop the younger, who at the age of twenty-five years had gone from Suffolk to Massachusetts as assistant to his father, an important Puritan leader, and governor of the Company of the Massachusetts Bay. Becoming Governor of Connecticut for a time, the son later returned to England and renewed contacts with British men of science, returning afterwards to America and resuming his public service. His medicinal prescriptions became famous; he mined for lead, tin and copper; he manufactured salt, glass and iron; he produced potash, saltpetre, alum, wood pitch and tar, and indigo; he built up the first scientific library in America; and he promoted the first American chemical stock company. In celebration of the tercentenary, the American journal *Chemical Industries* has published a supplement entitled "Chemical Industry's Contribution to the Nation: 1635–1935", a pleasantly presented and lavishly illustrated issue of 176 pages, which surveys the progress of chemical industry in the United States and includes a list of important commercial chemicals manufactured in that country. The chapter describing the *raison d'être* and public service of the Chemical Foundation opens with the following statement: "The establishment of a self-contained synthetic organic chemical industry in the United States is the only thing of substantial value which we got out of the war. Its establishment meant more to the American people than reparations or territory. . . . The value of this industry to the American people is inestimable."

International Broadcasting Union

ACCORDING to a report in *World Radio* for July 5, the International Broadcasting Union concluded its annual meeting on June 26, at Warsaw. Representatives of broadcasting organisations in twenty European States and in the United States of America were present. It was stated during the course of the session that the potential audience of listeners at the beginning of June has reached at least 200 millions. Among the more important business of the conference was the decision to organise a limited number of international programmes each year, in the form of discourses in which direct contact will be established between the greatest contemporary leaders in science and art, and listeners in the various countries of the Union. The progress in technical precision in broadcasting stations in recent years is illustrated by the results obtained at the Union's central observation laboratory in Brussels. Whereas ten years ago stations were known to fluctuate a few thousand cycles per second from their normal frequency during the course of a few hours, to-day the principal European stations do not fluctuate more than one or two cycles in a month from their established frequency, which in many cases is of the order of one million cycles per second. This meeting formally marked the conclusion of the first ten years of the Union's activities; and it witnessed also the passing from the office of president of Vice-Admiral Sir Charles Carpendale (a controller of the B.B.C.) who has been president of the Union since its foundation. Very warm tributes were paid to Sir Charles for his services in the cause of international broadcasting. The new president of the Union is M. Maurice Rambert, administrateur-délégué of the Société Suisse de Radiodiffusion.

Television in Germany

THE Berlin correspondent of *World Radio* states that although the German Broadcasting Company inaugurated its experimental high-definition television service on March 22 last, suitable receivers are not

yet available to the public, and when they are produced they will cost £30–£100 each. Both the German Post Office and the Broadcasting Company are, however, eager to provide the public with means whereby they can form an opinion of the entertainment value of the new service. Accordingly, the Post Office has opened a televiewing room in Berlin where reception is demonstrated every morning. Also, in co-operation with the German Listeners' Association, four similar rooms have been opened in other parts of the city where the public can witness the reception of the evening programmes. No charge is made for admittance, although to prevent undue crowding, tickets are issued and the attendance of each person is limited to half an hour. Thus during an evening programme of one hour and a half, three groups of 40–50 persons can have a demonstration at each centre. It is intended to extend these free facilities so that television, even in its present stage, will not be limited to the small group of persons who are financially in a position to buy apparatus.

Visibility Distance of Pedestrians

TESTS were carried out last year by the Massachusetts Highway Accident Survey with the object of finding out by actual experiment the distance at which the driver of a motor vehicle can see a pedestrian who is walking along the side of a highway at night. The tests are analysed and discussed in a paper by P. Moon and R. C. Warring (*J. Franklin Inst.*, March). The principal conclusions arrived at are that the visibility of a pedestrian walking along a highway at night is increased by roughly 50 per cent by showing a small area of white such as a handkerchief. Three reflector buttons, such as those employed in reflecting type highway signs, worn with dark clothing increase the visibility distance by 100 per cent, the same as that produced by a large area of white. It was found that the maximum safe speed at night was approximately 30 m.p.h., but if there was no glare from passing cars it was 40 m.p.h. These speeds are the optimum values. The time lag of the driver seems to vary between 0·5 sec. and 1 sec. even when the surprise element is lacking. On unlighted roads the type of the pavement and the speed of the car have little effect on the visibility distance. The tests show that it is advisable not to have the candle-power of the headlamps less than 32. Experience shows that depressing the headlamp beams so as to diminish glare reduces the visibility distance. Another important conclusion is that highway lighting does not increase visibility distance unless the average luminosity of the pavement is above the chromatic threshold, which is generally taken to be of the order 0·05 lumen per square foot.

The *Camionale* Genoa-Serravalle for Lorry Traffic

THE handling of the large import and export traffic of Genoa is a problem that has been studied by many Italian Governments. A satisfactory solution has now been found. A full description of the first section of the new motor road for heavy lorries (*camions*) called the *Camionale* is published in *Engineering* of June 28. The electrification of the railway from Genoa to Ronco over the Giovi mountain range in 1916 increased the capacity of the line more than four times. When this proved insufficient, a more direct electric railway was projected between Genoa and Arquata, necessitating the construction of a tunnel ten miles long through the Giovi mountains. The development of motor road transport and the success of the *autostrada* connecting Milan and Como, Naples and Pompeii, etc., created a new situation. The autostrada are characterised by the absence of practically all crossings and have minimum gradients and curves of long radius. No pedestrians are allowed on them. The new motor road, or Camionale, will ultimately join Genoa with Milan and Turin, and the projected electric railway has been abandoned. The Camionale starts from a large square near the Port of Genoa and traverses the Promontorio and Belvedere Hills by means of two long tunnels. After passing through many further tunnels, the road passes over the Montanesi torrent by means of a picturesque viaduct. In the Littorio tunnel, 2,926 ft. in length, the road reaches its highest altitude, 1,255 ft. above sea-level, at a distance of 13 miles from the terminal square at Genoa. The terminus at Serravalle Scrivia is 31 miles distant from Genoa. The geological conditions made the construction of the Camionale very difficult. The width of the road is 10 metres (32 ft. 10 in.). The total cost of construction of the Camionale is about 3½ million sterling at the present rate of exchange.

Australian Institute of Agricultural Science

IN January 1935 the Australian Institute of Agricultural Science was inaugurated, with Prof. A. E. V. Richardson, of the Waite Institute, as its first president. The presidential message states that "the major work of the Institute will be the development of an *esprit de corps* among the members of the profession throughout the Commonwealth, and in assisting in the formation of a public opinion which will insist that the agricultural and pastoral resources of Australia should be developed by the best known methods and utilised to the best advantage attainable". The constitution provides for periodical meetings of the Institute and its local branches, and also for the publication of a journal of which the first number has now appeared (vol. 1, No. 1, March 1935). It is intended that this journal shall be devoted to the publication of leading articles, reviews of present states of knowledge, research papers, technical notes and other items of a professional and general nature. The current number gives some indication of the wide field of interests it is proposed to cover. Contributed articles deal with agricultural science in the Soviet Union, and with rural relief and agricultural extension. The economic side is catered for by an article dealing with commerce and agricultural research and also by abstracts of a discussion on "Plant Quarantine" at the Melbourne meeting of the Australian and New Zealand Association for the Advancement of Science. The technical notes deal with various problems in agricultural plant physiology, entomology and pathology, while a column of

personal notes will help to keep the members of the Institute in touch with one another. If the present programme is continued, both the Institute and the *Journal* should help to fill the need that has long been felt for an organisation, commonwealth in scope, through which the views of the agricultural profession can be expressed.

Monographs of Physiology

THE rapid advance in our knowledge in every branch of scientific inquiry makes it difficult or impossible for investigators to follow the work which is being carried out in other fields than their own in any great detail. Even in their own particular sphere, they must rely for their knowledge of the literature to a certain extent upon the abstract and review journals. For this reason, we welcome the short monographs on different subjects which are now being published in Paris: the earlier series dealt with problems of physics and physical chemistry, but during the past year various monographs on physiological questions have been issued (Actualités Scientifiques et Industrielles. Nos. 113, 135 and 136, 178 and 179. 1934. Paris: Hermann et Cie). No. 113 in the series, by T. Cahn and J. Houget, gives a short account of the biochemistry of muscular contraction. The four chapters deal with the chemical changes occurring in a muscle extract, in an isolated muscle and in the intact animal during muscular work: the fourth summarises our knowledge. There are no references. Nos. 135 and 136, by Z. M. Bacq, give short accounts of sympathicomimetic substances and of the hormones and vitamins: bibliographies are included. The first gives a brief account of substances which produce the same, or similar, effects in the body as stimulation of the true sympathetic nerves, and discusses their mode of action. The second reviews briefly our present knowledge of the hormones and vitamins, especially from the point of view of the minuteness of the quantity which is active in the body. Nos. 178 and 179, by F. Kayser, deal with the biochemistry and physiology of creatine and creatinine, including their metabolism in health and disease. The subject is treated more fully than in the other monographs and the bibliography occupies about one third of each volume. Each gives an excellent review of our present knowledge of the functions of these compounds in the body, and is worth perusal by those interested.

University Degrees in Engineering

THE series of articles in the *Engineer* on "University Degrees in Engineering", to which we directed attention some time ago, have now been republished as a booklet (London: Morgan Brothers (Publishers), Ltd., 1*s*.). The author of the articles is Dr. T. W. Chalmers, and the survey has been prepared from information contained in official publications of the nineteen universities of Great Britain and Ireland. The survey does not pretend to cover all the essential features of the regulations, and matters connected with matriculation and entrance examinations have been excluded. The booklet should prove of use to everyone interested in engineering education.

Rabies in South Africa

IN the *Onderstepoort Journal of Veterinary Science and Animal Industry* for October 1934 (3, No. 2, p. 335), attention is directed to the increase in South Africa in the incidence of rabies in 1933 over 1932. The disease occurs, and appears to be spreading, among the small wild carnivora (*Viverridæ*). The disease was definitely proved in twenty animals, and in addition nine calves and three cows almost certainly died from it. There were six cases in man, transmitted once by a dog, twice by the domestic cat, once by a wild cat, and twice by the yellow mungoose (*Cynictis*).

The Case for Vivisection

AN article with this title, by a 'layman', Mr. J. Alderson, appears in the Research Defence Society's journal the *Fight against Disease* (No. 2, 1935). The author points out that experiments on animals in Great Britain are rigorously controlled by Act of Parliament; but it is his conviction that were there no such Act, vivisection would be carried out just as humanely as it is now, for a love of animals and abhorrence of wilful cruelty are as evident among medical men as among other citizens. He concludes by stating that he feels he must support and defend the work on account of the discoveries made through experiments on animals, and that whenever relevant information can be so obtained, it is our duty to encourage and support it.

Nutrition Research at the Mellon Institute

DURING 1934, Dr. Gerald J. Cox and Miss Mary L. Dodds, working on a fellowship at Mellon Institute of Industrial Research, investigated fundamental causes of tooth decay. Their work suggested the existence of a factor which, if present in the diet during a critical period of tooth formation, will aid in the construction of teeth resistant to decay. This research is to be continued, along broad lines, through a grant for a period of one year from the Buhl Foundation of Pittsburgh. The investigation, which will be known as the Institute's multiple fellowship on nutrition, will be carried on by Dr. Cox as senior fellow, Miss Dodds as the junior incumbent, and W. E. Walker as the assistant, in the Department of Research in Pure Chemistry of the Institute. It is planned first to determine definitely whether or not this factor actually exists, and, if so, its nature, properties, distribution and extraction. Secondly, studies will be made of physiological processes which are likely to influence the development of dental caries.

Award for Research in Fruit Growing

IN 1920 Miss L. Jones-Bateman of Cae Glas, Abergele, presented to the Royal Horticultural Society a valuable silver-gilt replica of the Warwick Vase, to be used for the encouragement of fruit production. It has accordingly been decided to offer it triennially for researches in the growing of hardy fruits, figs, grapes and peaches in the open or under glass, and it is available for award in 1935. Candidates

should submit accounts of their work by October 31. The work dealt with must have been carried out by the candidate in the United Kingdom mainly during the past five years. Further particulars may be obtained from the Secretary, Royal Horticultural Society, Vincent Square, Westminster, S.W.1.

Rockefeller Medical Fellowships

THE Medical Research Council announces that the following awards of travelling fellowships for the academic year 1935–36 have been made on behalf of the Rockefeller Foundation of New York: Dr. D. F. Anderson, professor of midwifery and gynæcology, Anderson College of Medicine, Glasgow; Mr. N. R. Barrett, demonstrator of anatomy and chief assistant to the Surgical Unit, St. Thomas's Hospital, London; Mr. A. C. P. Campbell, clinical tutor in medicine, Royal Infirmary, Edinburgh, and assistant lecturer, Department of Pathology, University of Edinburgh; Mr. D. H. K. Lee, Sharpey Scholar, Department of Physiology, University College, London; Mr. J. E. A. O'Connell, demonstrator in anatomy, St. Bartholomew's Hospital Medical School, London; Mr. R. Walmsley, assistant in anatomy, University of Edinburgh. All the fellowships awarded this year are tenable in the United States.

International Medical Post-Graduate Congress

THE seventh International Medical Post-Graduate Congress of the Tomarkin Foundation, New York, which has been organised under the auspices of the Université Libre de Bruxelles, will be held at Brussels on September 12–19 and at Spa on September 20–October 2. The proceedings at Brussels will include an international commemoration of Pierre Curie and Mme. Curie by a discussion on cancer, in which the Tomarkin Foundation will be assisted by the International Union against Cancer, and communications on tropical, subtropical and infectious diseases, and neurology; while the Spa meeting will be devoted to diseases of the cardio-vascular system and diseases of the blood. Papers on miscellaneous topics will be read at both meetings. The subscription terms are as follows: Full Congress, 80 belgas; half Congress, (Brussels or Spa), 50 belgas; single section, 30 belgas. On termination of the Congress, a visit will be paid to the principal Italian universities (Milan, Pavia, Bologna, Florence and Rome) and the most important sanitary institutes. The tour will last 10–12 days and the inclusive fare will be about 1,500 lire. Further information can be obtained from the Secretary, Tomarkin Foundation, 97 rue aux Laines, Bruxelles.

Announcements

PROF. JEAN LEPINE, Dean of the Lyons Faculty of Medicine, has been elected a member of the French Academy of Moral and Political Sciences.

THE Secretary of State for the Colonies has made the following appointments: Mr. J. M. Taylor, to be chief fruit inspector, Palestine; Mr. A. H. Weir, senior assistant conservator of forests, to be assistant deputy conservator of forests, Nigeria; Mr. A. E. Colman-Doscas, agricultural field officer, Federated Malay States, to be State agricultural officer, Johore; Mr. J. C. Nauen, horticulturist, Bermuda, to be assistant curator, Gardens Departments, Straits Settlements; Mr. R. O. Williams, assistant director of agriculture, Trinidad, to be chief horticultural officer, Palestine.

THERE are at present fourteen different localities in the Soviet Union for squadrons of sanitary aviation, and their number will be considerably increased in the course of the year. The Moscow squadron which was established in the spring of 1934 has already flown 534 hours and covered 67,680 kilometres in transporting 28 sick or wounded persons, 34 doctors, 48 litres of blood for transfusion and 500 kgm. of medical apparatus.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

A probationary assistant lecturer in mathematics in University College, Bangor—The Registrar (July 15).

A lecturer in mechanical and civil engineering in the Technical College, Sunderland—The Chief Education Officer, Education Offices, 15, John Street, Sunderland (July 16).

A resident tutor (male) in geography at the Borough Road College, Isleworth—Principal (July 17).

A junior forestry inspector in the Department of Lands, Irish Free State—Secretary, Civil Service Commission, 45 Upper O'Connell Street, Dublin, C.8 (July 18).

A teacher with qualifications in zoology, botany and chemistry in the Northampton College of Technology—Secretary, Education Office, Northampton (July 18).

An assistant teacher of mining subjects in the Doncaster Technical College—Secretary, Education Offices, Doncaster (July 19).

A woman lecturer in mathematics and biology or geography in the Swansea Training College for Women—The Director of Education, The Guildhall, Swansea (July 19).

An assistant to the secretaries of the Institution of Professional Civil Servants—Honorary Secretary (July 20).

Assistant civil engineers in the Civil Engineer-in-Chief's Department, Admiralty and H.M. Naval Establishment—The Civil Engineer-in-Chief, Admiralty, London, S.W.1 (July 31).

An assistant lecturer in physiology in University College, Cardiff—The Registrar (Aug. 31).

An assistant in the Department of Mechanical Engineering, Guildford Technical College—The Director.

An assistant lecturer in civil engineering in the Battersea Polytechnic, London, S.W.11—The Principal.

An inspector of machinery in the Mines Department of the Gold Coast Government—Crown Agents for the Colonies, 4 Millbank, S.W.1, quoting M/3793.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 71.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Quantum Mechanics and Physical Reality

IN a recent article by A. Einstein, B. Podolsky and N. Rosen, which appeared in the *Physical Review* of May 15, and was reviewed in NATURE of June 22, the question of the completeness of quantum mechanical description has been discussed on the basis of a "criterion of physical reality", which the authors formulate as follows: "If, without in any way disturbing a system, we can predict with certainty the value of a physical quantity, then there exists an element of physical reality corresponding to this physical quantity".

Since, as the authors show, it is always possible in quantum theory, just as in classical theory, to predict the value of any variable involved in the description of a mechanical system from measurements performed on other systems, which have only temporarily been in interaction with the system under investigation; and since in contrast to classical mechanics it is never possible in quantum mechanics to assign definite values to both of two conjugate variables, the authors conclude from their criterion that quantum mechanical description of physical reality is incomplete.

I should like to point out, however, that the named criterion contains an essential ambiguity when it is applied to problems of quantum mechanics. It is true that in the measurements under consideration any direct mechanical interaction of the system and the measuring agencies is excluded, but a closer examination reveals that the procedure of measurements has an essential influence on the conditions on which the very definition of the physical quantities in question rests. Since these conditions must be considered as an inherent element of any phenomenon to which the term "physical reality" can be unambiguously applied, the conclusion of the above-mentioned authors would not appear to be justified. A fuller development of this argument will be given in an article to be published shortly in the *Physical Review*.

Isotopic Constitution of Palladium and Gold

THESE two elements are among the few from which positively charged atoms have not been obtained by means of volatile compounds introduced into the electrical discharge or by means of anode rays. In a letter in NATURE[1], the possibility of using the ions from a high-frequency spark was pointed out. With the mass-spectrograph [recently described in NATURE[2]] it was found that palladium consists of six isotopes with atomic masses 102, 104, 105, 106, 108, 110. They could be compared with doubly-charged platinum and gold atoms which were present as a slight impurity. The four middle components are about equally strong; the one at 110 is weaker, and the lightest at 102 is the faintest.

From its atomic weight 197·2 and the behaviour of other elements of odd atomic number, it was anticipated that gold would have two isotopes at 197 and 199, one about ten times the intensity of the other. It was somewhat of a surprise to find that no second component could be found. Exposures were made with 300 and 500 times the time required to show the main line, and failed to show any trace of a heavier isotope. It is thus very probable that gold has only one component, and that the accepted atomic weight is too high.

Platinum Isotopes and their Nuclear Spin

Using a water-cooled hollow cathode of a new design, the hyperfine structure of the arc lines of platinum λλ 3408 and 3042 A. have been studied. These two lines have a common lower level $5d^96s^2a^3F_4$; and the similarity of their structure patterns leads to the conclusion that in neither case is the upper level split. The lines have the following structure:

Wave-length (in I.A.)	Classification[1]	Structure (in cm.$^{-1}$)
3408·13	$5d^96s^2\ a^3F_4 - 5d^96s6p\ z^5D^0_4$	+ 0·161 (5), 0·000 (18), − 0·086 (7), − 0·176 (1), − 0·314 (4). (vide Fig. 1)
3042·75	$5d^96s^2\ a^3F_4 - 5d^96s6p\ z^5G^0_5$	+ 0·162 (5), 0·000 (18) − 0·087 (7), − 0·174 (1), − 0·314 (4).

An examination of the structure leads to the unique inference that the three central components 0·000 (18), − 0·086 (7) and − 0·176 (1) have to be ascribed to the even isotopes 196, 194 and 192 respectively, the remaining two components being due to the odd isotope 195 with a nuclear spin of $\frac{1}{2}h/2\pi$. The centre of gravity of the latter components falls at − 0·050 cm.$^{-1}$ between the bright components due to 196 and 194. The deeper level $5d^96sa^3D_2$ shows no measurable isotopic displacement. The hyperfine levels in platinum are inverted. These results are confirmed by the analysis of eight other arc lines of platinum, namely, 2998, 2929, 2734, 2719, 2705, 2702, 2659 and 2650 A. Neglecting

isotopes of small abundance, the isotopes of platinum, purely from hyperfine structure data, in decreasing order of their relative abundance, are 196 (18), 195 (9), 194 (7) and 192 (1). The relative isotopic abundance given above is from eye-estimates of the intensities of the components and is to be checked by microphotometric measurements.

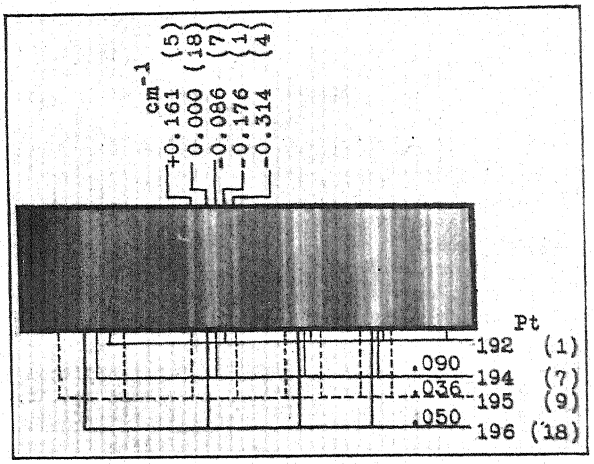

FIG. 1. Structure pattern of Pt I λ 3408·13 A. ($a^3F_4 - z^3D^0_4$) obtained by a Hilger quartz Lummer plate, 3·45 mm. thick and 20 cm. long.

Platinum exhibits a positive isotope shift, that is, the heaviest isotope lies deepest. The nucleus of platinum can be considered as having 39 α-particles, with neutrons to make up the mass number. The observed positive isotope shift is consistent with our previous generalisation[2] that even atomic number "elements whose nuclei contain an odd number of α-particles exhibit positive isotope shift and those with even number a negative displacement".

Details will soon appear in the *Proceedings of the Indian Academy of Sciences*.

Selective Absorption of Slow Neutrons

IN our letter of April 12[1], we mentioned that the absorption of slow neutrons by iodine was apparently greater when the induced β-ray activity of an iodine detector was used as a measure of the number of neutrons transmitted than when detectors of silver or rhodium were employed. We have now confirmed this selective absorption and have extended the measurements to absorbers of silver and of copper, where analogous though somewhat less marked selectivity is found. The accompanying table shows the activity (expressed as a fraction of that obtained in the absence of the absorber) when hollow cylinders of silver (1·0 gm. cm.$^{-2}$), copper (4·5 gm. cm.$^{-2}$) and iodine (2 gm. cm.$^{-2}$) were placed in turn around various detectors, themselves in the form of hollow cylinders. A layer of cadmium, sufficiently thick to absorb nearly all slow neutrons striking it, was always placed inside each detector during irradiation, so that when the absorber was in place, neutrons reaching the detector must have passed once, and only once, through the absorber. The irradiation was performed within a 4 cm. cavity in a large block of wax, the source being at 9 cm. from the centre of the cavity. It seems clear that different nuclei prefer neutrons of different velocities.

Absorber / Detector	Silver	Copper	Iodine
Silver (25 sec.)	0·50 ± 0·03	0·72 ± 0·04	0·85 ± 0·05
Silver (150 sec.)	0·51 ± 0·03	0·70 ± 0·04	0·95 ± 0·06
Copper (5 min.)	0·62 ± 0·05	0·72 ± 0·045	0·89 ± 0·06
Copper (10 hr.)	—	0·62 ± 0·05	0·90 ± 0·07
Iodine (25 min.)	0·72 ± 0·025	0·76 ± 0·025	0·68 ± 0·03
Rhodium (44 sec.)	0·69 ± 0·025	0·80 ± 0·04	0·91 ± 0·04
Silver (25 sec.) 'Cold' neutrons	0·41 ± 0·03	—	—

In connexion with the effect of temperature on the properties of neutrons, which we reported in our last letter and which is supported (at least as regards several elements) by recent work of Fermi and his collaborators[2], we should like it to be made clear that numerical values of the ratio of the activities induced by neutrons of different 'temperatures' are significant only with respect to the geometrical conditions of the particular experiment in question. An important factor is the thickness of the hydrogenous layer the temperature of which is altered. If this layer be thin in relation to the mean free path for *scattering* of the thermal neutrons, a new 'temperature' cannot be set up; if, on the other hand, the layer be so thick that there is a large chance that a thermal neutron will be *absorbed* in passing through it, the observed change in the induced activity will be a differential effect of the changes in absorption coefficients of the wax and of the specimen. It might be possible to obtain rough values for the free paths for scattering and absorption from observations of the temperature effects with layers of different thicknesses. The thickness of the detector may also be of great importance; for example, 'cold' (90° K.) and 'warm' neutrons were allowed in turn to fall on the *outer* surface of a hollow silver cylinder the wall thickness of which was one millimetre. No difference in the activities of the *inner* surface could be observed, though a very thin silver cylinder under identical conditions showed an increase of 17 per cent at the lower temperature. It is clear that the thermal neutrons are much absorbed in a millimetre of silver, so that with a thick specimen the increased activity is mainly confined to the outer layers.

Measurements of the ratio of the activity at 90° K. to that at 290° K. have given the following figures:

Copper (5 minute period), 1·25 ± 0·05; silver (25 sec.), 1·17 ± 0·04; iodine (25 min.), 1·10 ± 0·03.

The thickness of wax cooled was in these experiments 2·2 cm., and the geometry was otherwise slightly different from that of the earlier measurements, in which we found ratios of 1·26 and 0·84 for silver and iodine respectively. We had not previously investigated copper. The decrease which we previously found with iodine has turned out to be due to the presence of boron in the glass container, We have found, using both iodine and silver detectors.

that the absorption of slow neutrons by boron is greater for cold than for warm neutrons. A similar increase occurs in the absorption coefficient of silver, as is shown in the table, while a small increase in the absorption by cadmium has been found by Dunning and his collaborators[3].

The Radium Committee of the Medical Research Council has again most kindly given us, through Prof. S. Russ, supplies of radon for the sources used.

Absorption Continuum due to Quasi-Molecules of Calcium in Dwarf Stars of Type *M*

I FOUND several years ago that the dwarf stars of type *M* show a singular depression between the line λ 4227 and the *G* band. This phenomenon appears to be intimately connected with the intrinsic luminosity of the stars, and forms a criterion which can be used with low dispersion to a very faint limit in apparent magnitude. As the effect is therefore of considerable importance, I have arranged to study it more closely in slit spectra of larger dispersion by comparing a typical giant and a typical dwarf of type *M*. The stars chosen are:

Boss 3584, *gM*2, abs. mag. − 0·5 (Mount Wilson spectroscopic value),

Boss 2935, *dM*2, abs. mag. + 10·7 (Mount Wilson spectroscopic value).

The Cassegrain spectrograph on the 40-inch Grubb reflector of the Stockholm Observatory was used in the one-prism combination with a fine slit. The photographic energy curves of the two stars were obtained in great detail. The run of the observed differences between *B* 2935 and *B* 3584, when minor fluctuations due to various lines are eliminated, are illustrated in Fig. 1. The observed absorption continuum in B 2935 extends from λ 4227 in a very asymmetrical way, mainly towards long wave-lengths, and is noticeable between the wave-lengths λ 4120 and λ 4650. The results are entirely confirmed by analysis of the two stars with a slitless spectrograph of low dispersion.

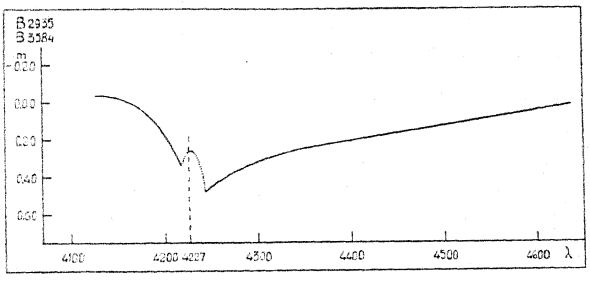

FIG. 1.

A clue to an understanding of the phenomenon is probably the continuous spectrum around the resonance line of Ca, λ 4227, which has been observed by H. Hamada[1] to extend between λ 3980 and λ 5100, and is ascribed by him to a quasi-molecule of calcium, which in the excited state consists of one atom in the $4s^1S_0$ level and one in the $4p^1P_1$ level. In our case, where the spectrum of the quasi-molecule appears in absorption, the original state should be two atoms in the ground level $4s^1S_0$. The energy of one of these atoms may be raised by absorption of a light quantum $4s^1S_0 - 4p^1P_1$, at a time when the two atoms lie close to one another. Since the polarisation effects on the potential curve are stronger in the excited state than in the unexcited state, the difference in energy between the two levels will shift from the normal value for the resonance line. The most common case of large distances between the atoms corresponds to the maximum of absorption at the resonance line itself. It is clear that the strength of the continuous absorption will be highly dependent on the average density of the Ca gas, and thereby on the gravity *g* at the surface of the star. We should, in fact, expect the mass coefficient of absorption at a point in the continuous spectrum of the quasi-molecule to vary in direct proportion to the density of neutral Ca gas, which with equal numbers of neutral atoms in the respective atmospheres should mean a variation proportional to *g*. However, the variation with *g* will be increased considerably by the greater number of neutral atoms of calcium in the atmosphere of the dwarf, which is evident from the behaviour of the arc lines of calcium. The values of *g* for the giant and the dwarf will stand in a proportion of about 1 : 4,000 to each other.

The absorption continuum in question will be largely responsible for the great intensity and marked asymmetry of the line λ 4227 when observed with low dispersion. The intensity and asymmetry increase rapidly with decreasing absolute brightness of the stars in the main series[2].

Origin and Nature of the Egg Case in the Crustacea

THE origin and nature of the membranes which surround the eggs of decapod Crustacea and the means whereby the eggs are attached to the pleopods of the female have both hitherto been obscure. Herrick[1,2] gives a good review of the literature. Following up previous work (Yonge[3]) on the function of the tegumental glands in the decapods, I have found that the eggs are surrounded by two secreted membranes. The inner of these gives positive reactions to every chitin test; the outer is undoubtedly composed of the same material as the cuticle which everywhere forms the outer layer of the integument, and is secreted by the tegumental glands (for details see Yonge[3]).

The ovarian egg possesses neither of these membranes, being surrounded only by a vitelline or primary egg membrane. Eggs obtained as they left the oviduct of a laying lobster possessed only the inner, chitinous membrane. At this period the epithelial cells in the oviduct are greatly elongated and resemble the chitinogenous epithelium at the time when this is secreting new chitin: they clearly secrete this inner membrane. The so-called cement

glands, which occur in great numbers on the pleopods of the female only, and resemble in all respects the tegumental glands, secrete the outer membrane. This not only surrounds the eggs but also attaches them, by a twisted strand, to the pleopods. I have shown (Yonge[3]) that the cuticle secreted by the tegumental glands must have a very low surface tension, and this property would explain how the secretion from the cement glands wraps round the eggs and attaches these to the pleopods. Further evidence was obtained by experiments on the swelling of the eggs in various solutions, which agrees with work (unpublished) on the permeability of the uncalcified integument in *Homarus*.

Identical conditions were found in both Astacura and Brachyura, while Miss M. L. Mawson, who has been working under my direction, finds similar conditions in *Chirocephalus*. Here also the oviduct secretes a thin chitinous membrane, while unicellular glands opening into the uterus add a rugose coat giving the major reactions of the cuticle. Here the eggs are not attached but the restricted permeability of the cuticle, chitin alone being freely permeable (Yonge, unpublished work), is probably of supreme importance in protection. The presence of the cuticle will also permit of hatching by osmotic forces (see Needham[4] for literature).

Conditions in the Insecta provide an interesting parallel. Wigglesworth[5] has shown that in *Rhodnius* the integument consists of an epicuticle, closely resembling the cuticle of the Crustacea, and an underlying endocuticle which is chitinous. But both are formed by the epithelium, the dermal glands secreting the exuvial fluid (the function of which is performed by wandering cells in the decapods, Yonge[3]). Wigglesworth suggests that the œnocytes synthesise some of the non-chitinous constituents of the integument, and it seems probable that they are at least analogous with the tegumental glands of the Crustacea. They persist in the adult but are active only in the female, when he further suggests they form the material of the exclusively non-chitinous egg-case, which is probably similar to the outer membrane of the Crustacean egg.

Tegumental glands in the Arthropoda are organs of the greatest importance. In the Decapoda alone they secrete the cuticle, the protective and/or cementing membrane of the egg, and the material which secures the statoliths (Lang and Yonge[6]). They are being extensively investigated in this laboratory.

The Chromosome Micelle and the Banded Structure of Chromosomes in the Salivary Gland

GREAT interest has been aroused in cytological circles by the discovery that individual chromosomes in the salivary glands of *Drosophila*, *Sciara*, *Chironomus* . . . may be characterised by successions of light and dark bands and regions which are arranged in definite patterns[1].

I have recently made suggestions[2,3] as to the molecular structure of chromosomes, being guided as regards material by the behaviour of chromosomes in the mitoting cell and the requirements of genetics, as regards treatment by our present knowledge of the structure of coarse animal and vegetable fibres[4]. It is interesting to notice that the molecular structure postulated provides also a simple explanation and interpretation of the banded structure of these giant chromosomes.

The chromosome has protein and nucleic acid constituents. I locate the genetic identity of a chromosome in its characteristic protein constituent and define the *protein pattern* of an individual as a sequence of protein molecules of the classical type—peptide linked amino acids—

. . . NH.CO.CH*P*.NH.CO.CH*Q*.NH.CO.CH*R*.NH . . .

placed end to end in salt linkages. The protein pattern may therefore be expressed in terms of side chains . . . *PQR* . . . and in the most general case of n molecules end to end may be written in the form of a sequence of sequences of units

$$A_1B_1C_1 \ldots X_1Y_1Z_1, A_2B_2C_2 \ldots \ldots, X_nY_nZ_n \quad (1)$$

The essential requirement of genetics—that 'genes' form a linear array—is thereby met, and interpreted: the genetic identity of a chromosome resides in the nature of its protein pattern and this is expressible in a one-dimensional sequence.

To maintain this linearity of specification, we envisage the chromosome micelle, so far as the protein constituent is concerned, as an aggregate of identical sequences of molecules, the protein patterns, lying side by side. Owing to the large preponderance of basic acids in these molecules and the consequent high degree of ionisation for $p\mathrm{H} < 9$, say, these will lie on and themselves constitute a quasicylindrical surface. The molecules of nucleic acid[5], which possess four acidic centres of ionisation, for $p\mathrm{H} > 4$, say, will form salt linkages[6] with quartets of basic side chains belonging to parallel and neighbouring protein molecules. Owing to the azimuthal symmetry required by genetic considerations, the nucleic acid will polymerise in rings around the micelle. Where there are basic residues in the protein complex, there will be rings of nucleic acid; where basic residues are lacking, nucleic acid rings will also be lacking.

The Feulgen reaction, which is specific for nucleic acid, has long been recognised as a method for studying the morphology of chromosomes. For our micelle, the use of the Feulgen reaction means that attention is directed, not to the chemical nature of the chromosome in general, but only to the distribution of basic as opposed to non-basic units in the protein pattern. We are in fact considering the chromosome as characterised not by its protein pattern (1) but by what may be called its *Feulgen pattern*:

$$NNO \ldots ONN, NON \ldots \ldots \ldots \ldots NNO \ldots \quad (2)$$

Here N is written wherever there is a basic unit in the protein pattern, since at that point there will be a ring of nucleic acid, and O where there is a non-basic unit, since here there will be no nucleic acid.

In the salivary gland the chromosome is in a state of very considerable extension. We should therefore expect it when properly treated[7] to show up, specially favourably, the detailed alternation of basic and non-basic units in the protein pattern which characterises the individual chromosome. The salivary chromosome is a compound structure consisting of a group

of homologous chromosomes in parallel. Where there is a high density of nucleic acid associated originally with each constituent chromosome, this will show up as a dark region; where the density is less there will be a less dark region; when the density falls too low, no dark region at all will be visible.

We therefore interpret the banded structure of the salivary chromosomes as due to the alternation of basic and non-basic units in the protein pattern and as such providing a picture—though an incomplete one—of the chemical situation. This interpretation is being worked out in detail. To illustrate the orders of magnitude involved, it may be added that when the chromosome micelle is fully extended, 100 entries in the protein or Feulgen pattern represents a length of 0·035 microns and that the average number of rings of nucleic acid in the case of clupein nucleate is one per 4·9 angstroms, giving about two thousand rings per micron[8].

The fact that chromomeres seen in the early stages of meiosis stain more deeply than the intermediate regions also allows of interpretation on these lines and accords well with the suggestion recently made[3] that in the contraction of chromosomes the differential distribution of nucleic acid along the length of the chromosome plays an important part.

Molecular Structure in Sisal, Coir and Oak

IN the course of an investigation on the general morphology and anatomy of *Agave sisalana*, X-ray photographs were taken in the Department of Physics, by courtesy of Dr. Leonard Huxley, of the fibres, and also of those of *coir*.

The X-ray photograph of sisal fibres (Fig. 1*a*) showed a pattern, which agrees with that obtained for cotton by other workers, and it can thus be inferred that the X-ray pattern of sisal is that of cellulose. The X-ray photograph obtained of stretched sisal fibre bears the same relation to the unstretched fibre as does the photograph of stretched cotton to that of unstretched cotton, from which it is also inferred that stretching acts on the crystallites (or micelles) in the sisal fibre in the same way as in that of cotton.

Coir was also photographed, and the X-ray pattern showed a striking difference from that of sisal, in that it consisted of two cellulose patterns at right angles to each other (Fig. 1*c*). These patterns were placed at 45° to the vertical. The coir pattern may be interpreted either as one spiral of crystallites, which runs at an angle of 45° round the fibre, or as two distinct spirals, which are at right angles to each other, but each running at 45° round the fibre and in opposite directions.

The part, if any, played by lignin has been investigated by chlorinating the lignin in the fibre by the Cross and Bevan method, and further by the removal of the lignin. No difference was shown in the X-ray pattern obtained from fibres treated in this way (Fig. 1*b*), except that the chlorinated fibres gave a less *intense* negative.

As sisal fibres have been shown to contain a somewhat low lignin component, coir fibres were chosen for comparative investigation, as containing a relatively high lignin percentage, and these similarly were chlorinated. Here, also, the photograph obtained from the treated fibres showed no difference in form from that of the untreated fibre. In both coir and sisal, however, the chlorinated fibres gave a less intense negative.

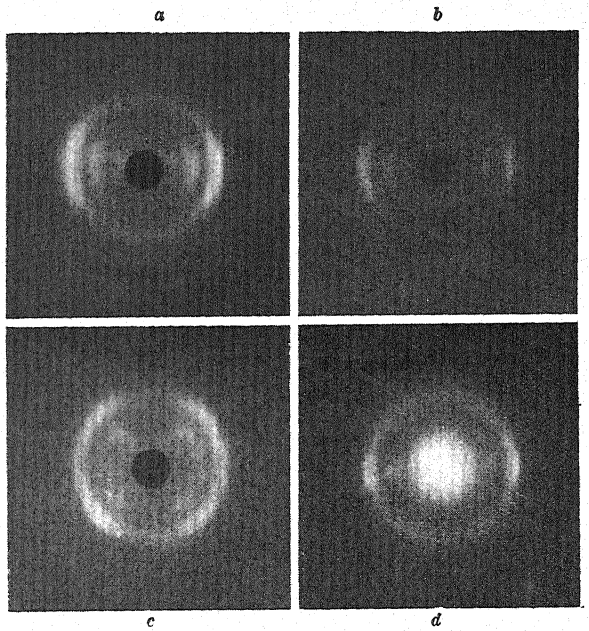

FIG. 1. X-ray photographs, taken by J. Hewitt, with fibre axis at right-angles to the X-ray beam. *a*. Sisal fibre. *b*. Delignified sisal fibre. *c*. Coir bristle. *d*. Heartwood of oak.

In a further test of the negative X-ray properties of lignin, that is, of its amorphous character, the wood of oak has been used, as having one of the highest known percentages. The photograph obtained showed, as in sisal and coir, a cellulose pattern, in which, however, the equatorial spots were sharp and not drawn out into arcs (Fig. 1*d*). It is inferred that the cellulose crystallites in oak lie parallel to the longitudinal axis of the tracheids and that they are almost perfectly orientated. This is not the case in pine wood, as illustrated by K. Freudenberg[1] in a model from the tracheids of pine. The model would suggest a photograph with two cellulose patterns at right angles to each other. The photograph of oak (Fig. 1*d*), however, agrees, to some extent, with the photographs of B. Schmidt[2] for the summer wood of ash and the spring wood of fir. Also, the almost perfect arrangement of the crystallites in oak as here recorded agrees with the statements of S. Pienkowski[3], that the cellulose crystallites are the more perfectly arranged in compact woods.

The X-ray investigations reported above show that sisal fibres have the X-ray pattern already known in cotton and therefore attributable to

cellulose. The double cellulose pattern found in coir admits at any rate of two interpretations.

The photographs, obtained after chlorination and other treatments, support the view that lignin is amorphous. The lesser intensity of the photographs may, however, have significance.

The results obtained from the wood of oak differ from those shown by the model of *Pinus* presented by Freudenberg, which, however, admits of a different interpretation, but they are probably consistent with those of Schmidt for ash and fir, and also would appear to support Pienkowski's statements (loc. cit.) concerning compact woods.

Registration of the Ionisation Curve of a Single α-Particle

IF an α-particle from a preparation *A* (Fig. 1) passes through a hole in the electrode *B*, it produces ions in the space between *B* and *C*. The ions drift with constant velocity in the homogeneous electric

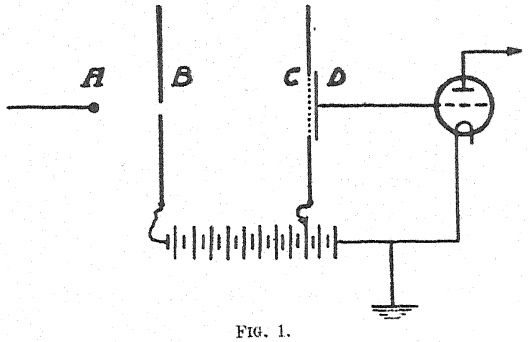

FIG. 1.

field between the electrodes. When the ion column has reached *C*, it passes through the meshes in the grid and produces a current $i(t)$ to the electrode *D*, which is connected to a four-valve amplifier. This current $i(t)$ would be expected to give a good picture of the ionisation curve. But as *D* has a capacity and is well insulated, the tension to be amplified is proportional to $\int_0^t i(t)\,dt$. Therefore, in order to obtain the ionisation curve after the amplification, we must differentiate the tension curve, and this is done electrically between the third and the fourth valve by the help of a resistance-capacity device having a very short time-constant.

The amplifier is connected to an oscillograph and the light-sensitive film or paper is placed on a rotating cylinder. The zero position is moved during the revolutions.

Fig. 2 shows an oscillogram obtained in this way. The α-particles which have depicted their ionisation curves in it, came from a very weak polonium preparation placed 2 cm. from *B*, so that the ionisation curves represent the last 2 cm. of their path.

It seems quite possible to register H-particles in the same way. Then, if the oscillogram is calibrated, it tells us at once the kind of the particle (height of the ionisation curve) and the length of its track (proportional to the length of the ionisation curve). Therefore, if the ionisation chamber is given a geometrical form adapted for very weak preparations, this instrument may be useful for the study of nuclear reactions.

A more detailed report will appear shortly.

Properties of Crystalline Magnesium Oxide

ARTIFICIALLY produced crystals of magnesium oxide (MgO) are now available commercially; since they are formed as a by-product in a commercial process, they are not expensive. Our samples were obtained from the Norton Company, Worcester, Mass., U.S.A. Most of the pieces of crystal are about 1 cm. × 1 cm. × 0·5 cm., but a few larger specimens up to 3 cm. × 3 cm. × 1 cm. are produced. Some specimens are quite clear, some are slightly yellow, and some are a little cloudy. The clear specimens are transparent to λ 2200. The crystal belongs to the cubic system, but most specimens show some double refraction owing to residual strains.

Brice and Strong[1] found the crystals to be resistant to attack by lithium, sodium, potassium and calcium. We have made quantitative tests by heating the crystal with various metals in small evacuated tubes; the tubes were kept at the specified temperatures for 1 hour. Potassium (400° C.), sodium (500° C.), lead (1,050° C.), magnesium (1,100° C.), and aluminium (1,100° C.) had no effect; calcium (1,050° C.) and copper (1,100° C.) etched the surface slightly. Thus the crystal is much more resistant than glass or quartz to penetration by metal vapours. X-ray analysis shows[2] that the crystal has a close-packed structure, which probably accounts for this property.

The material can be ground and polished by using successively graded emery, tin oxide and rouge. Windows can be sealed into soda glass of high expansion coefficient. (The coefficient for the crystal is 11×10^{-6}; our glass—determined by Messrs. Yates and Roulston—has a coefficient of $9{\cdot}6 \times 10^{-6}$ in the range 0°–100° C.) The glass appears to wet the crystal when molten, and adheres well when cold, forming a vacuum-tight seal. It is important that the edges of the crystal should be polished before

sealing in. As the cutting, polishing and sealing take some time, it is desirable to select, with a polariser, specimens comparatively free from strain. With the above precautions the probability of failure is small.

We wish to thank Prof. Brice, through whose courtesy we obtained samples before the material was regularly available.

Electrical Units and the I.E.C.

THE interesting note on Electric Units in NATURE of July 6, p. 15, is perhaps too definite in one important particular.

It is recognised that in addition to the three accepted units of length, mass and time a fourth unit is required for the specification of electrical quantities.

Prof. Giorgi, as is well known, desires the adoption of one of the International Units, and I understand prefers the International Ohm. But no decision on this point was reached at the recent I.E.C. meeting. In a letter dated June 27, 1935, and sent to me as chairman of the S.U.N. Commission of the International Union of Pure and Applied Physics, Dr. Kennelly, chairman of the Electric and Magnetic Units Committee of the I.E.C., after referring to possible quantities for the fourth unit, writes:

"It was decided that the choice should not be made before consulting the International Union of Physics S.U.N. Commission and the Comité International des Poids et Mesures Comité Consultatif d'Electricité".

He asks that the matter should be brought to the attention of the S.U.N. Commission of the International Union "as it would evidently be most regrettable if the choice and definition of the fourth fundamental and practical unit should lead in the future to incomplete agreement between the Practical Electrical Units used in Physics and in Electrotechnics".

Accordingly, I am taking steps to bring the matter to the attention of the S.U.N. Commission. A difference between the standards of the physicist and the engineer would be not merely regrettable but a disaster of the first order.

R. T. GLAZEBROOK,
Chairman of the Commission on Symbols, Units and Nomenclature of the International Union of Pure and Applied Physics.

Points from Foregoing Letters

PROF. NIELS BOHR announces his disagreement with the recently-expressed opinion by Prof. A. Einstein, B. Podolsky and N. Rosen that the quantum mechanics description of physical reality is incomplete, owing to the uncertainty principle, which states that the position and velocity of a particle cannot both be accurately known at the same time.

Using the ions from a high-frequency spark, Prof. A. J. Dempster has analysed palladium and gold by means of the mass-spectrograph. The results show six isotopes for palladium and the only one component for gold. The atomic weight of gold, if it has no isotopes, should be an integer, and the accepted value (197·2) may have to be revised.

Prof. B. Venkatesachar and L. Sibaiya identify certain components in the arc spectrum of platinum with its various isotopes (at. wt. 192, 194, 196, 195) and estimate roughly their relative abundance. As shown by the positive isotopic shift of the spectral components, the heaviest isotope lies deepest, as is generally the case in nuclei containing an odd number of alpha particles, of which platinum has 39.

Mr. J. R. Tillman and Dr. P. B. Moon find that the absorption coefficients of silver, iodine and copper for slow neutrons vary with the detector used. This indicates that the elements in question absorb selectively neutrons of different velocities. The authors also give the ratio of the activity at 90° and 290° K., and point out some of the factors that must be considered when determining the effect of temperature on the activity of the neutrons.

From the difference in the spectra of a typical giant star and a typical dwarf star (due to absorption of light in the region of wave-lengths 4100–4600 A.) Prof. Bertil Lindblad infers the presence of excited calcium molecules and deduces that the value of the gravitational constant g for the giant and the dwarf is in the ratio 1 : 4000.

The nature and origin of the membranes surrounding the eggs of the lobster and the means whereby the eggs are attached to the swimming limbs of the female are described by Prof. C. M. Yonge and compared with conditions in other marine animals.

Dr. D. M. Wrinch draws a picture of a chromosome as a sequence of protein molecules linked end to end by their acidic and basic groups, to satisfy the essential requirements of genetics that genes form a linear array. She interprets the banded structure of the salivary gland chromosome of the fruit fly as due to the alternation of basic and non-basic units in the protein pattern.

Dr. E. N. Miles Thomas and Mr. J. Hewitt describe the X-ray patterns of sisal, coir and oak. Sisal gives the usual cellulose pattern; the coir pattern may be interpreted either as one spiral of crystallites or as two distinct spirals at right-angles to each other, running in opposite directions at 45° round the fibre. In oak, the crystallites appear to lie parallel to the longitudinal axis of the wood cells (tracheids) and are almost perfectly orientated. The effect of chlorination upon the X-ray patterns supports the view that lignin is amorphous.

An apparatus by means of which the ionisation produced by a single alpha particle or by a proton can be directly registered is described by Dr. Hannes Alfvén. It may prove useful in the study of nuclear reactions leading to atomic disintegrations.

Prof. R. W. Ditchburn and Mr. J. Harding describe some properties of crystalline magnesium oxide, which is now commercially available. The crystal can be polished and sealed into soda glass, and is very resistant to attack by metal vapours.

Research Items

Stone Age Survivals in Ireland

A MOUSTERIAN tradition surviving into the Campignian is very clearly exemplified in the industry of Rathlin Island investigated by Mr. C. Blake Whelan. The dangers of chronological assumptions based on comparative typology are here exposed on the periphery of 'neolithic' migrations. A striking example is afforded by a cordate or sub-triangular hand-axe of fine grained stone, a surface find from one of the numerous late prehistoric stations spread over the Rathlin uplands (*Antiquaries J.*, **15**, 2), to which it is highly unlikely that a date earlier than 2500–2000 B.C. can be assigned. This dating is all the more probable in the light of the results of excavation, although the survival of the use of implements of fine grained rock to at least as late as the final Bronze Age or early Iron Age (500 B.C.) admits of a much later dating. It would be difficult to find a better example than this specimen of the survival of Levallois and Mousterian technique, upon which Goury, the present writer and others have based the postulate of an eastern focus at which, uninfluenced by any Upper Palæolithic technique, the Mousterian evolved into the Campignian and, moving westward, absorbed and devised new forms which preserved the heavy aspect of the ancestral technique. The specimen under notice is a faithful reproduction of the cordate or sub-triangular hand-axe of cave Mousterian universally figured as type specimens of this epoch some sixty thousand years earlier.

Divination in Melanesia

AMONG the Tanga people, who occupy islands off the coast of New Ireland, Mandated Territory of New Guinea, great ritual importance is attached to death, and at one time a divinatory ceremony was practised when sorcery was suspected as the cause. One such ceremony, which took place long ago, has been described in detail to Mr. F. L. S. Bell by two aged men who themselves had taken part (*Man*, **90**; 1935). It was performed in connexion with the unaccountable death of a young woman. The instrument of divination was a bamboo pole, about thirty feet long, to which was attached a bunch of highly perfumed leaves, believed by the natives to be a strong aphrodisiac. The ceremony was termed "Several men fish for the ghost", and it was believed that the leaves served as bait. The pole was raised on the shoulders of five or six men, who were distant relatives of the deceased. They then carried it to the place at which the woman was born, as the most likely spot at which her ghost would be found. When the pole became heavy on their shoulders as they marched, it was believed that they had encountered the ghost. It then fled to her husband's house, whither they followed it. Twenty men then clung to the pole, headed by one of the woman's cross-cousins, who began to question the ghost. It was essential that no one within the forbidden degrees should touch the pole, otherwise the ghost would not answer. The ghost was asked who was responsible for her death, individuals being mentioned by name. When the guilty person was named the pole began to vibrate violently and was drawn towards the interior of the house, the efforts of the twenty men, however strong, being unable to prevent it. When the pole ceased to vibrate the men withdrew and the pole was placed by the side of the woman's grave. No punishment followed, except the ill-repute of being a sorcerer and consequent ostracism.

Identical Twins

IN a lecture on twins (*Eugenics Rev.*, **27**, No. 1), Dr. J. A. Fraser Roberts reviewed the modern work on this subject. He favours a genetical rather than a physiological theory of identical twinning. A quiescent phase of the embryo occurs in the badger as well as the armadillo, but in the badger identical twins are unknown. Some identical human twins show mirror-image phenomena, but this is not true of the twins that are most nearly identical. It appears that mirror-image twins are due to a somewhat later separation of the embryo into two. The intelligence quotient of identical twins is not so largely inherited as stature and other physical characteristics. Nevertheless, it is concluded that even here heredity is more than three times as important as environment. Reference is made to the studies by Newman of twins reared apart, and it is suggested that similar comparisons should be made of twins reared together. The need for more accurate records of twin births by physicians is emphasised. Psychological studies should be made of the comparative effects of training on twins, following Gesell. The ideal would be a register and 'follow up' of all twin births.

Agranulocytic Angina

THIS is a rare disease characterised by severe sore-throat or tonsillitis ('angina') with fever and prostration, and frequently fatal. It was first described in 1922 by Werner Schultz (*Deutsch. med. Wochschr.*, **48**, 1495), and a review on the subject by Dr. E. W. Adams, with bibliography, has been recently issued by the Ministry of Health (Rep. on Pub. Health and Med. Subjects, No. 76. London: H.M. Stationery Office, 1935. 6*d*. net). A remarkable and characteristic feature of the disease, from which it derives its name, is a diminution in the number of leucocytes or white blood-cells from the normal of 10,000–12,000 to 1,000 or less per c. mm. of blood, with an almost complete disappearance of the polynuclear leucocytes ('granulocytes'), which normally constitute 75 per cent of the total leucocytes. About a thousand cases of the disease have now been described, of which only twenty-two have been recorded in the British Isles. It is more common in females, and the fatality in the earlier cases was more than 90 per cent. The causation is obscure, but evidence suggests the action of some toxic agent. Much accumulated evidence points to a connexion with the use of the drug 'amidopyrine', and a case appears to have been made out incriminating the benzamine group of drugs. Dr. Adams has collected 140 cases, with 74 deaths, following the administration of amidopyrine, and two single doses of 10 grains and 5 grains of this drug have been found to cause an immediate and striking diminution in the granulocyte and total white blood-cell counts. Pentose nucleotide appears to exert a curative action, the mortality in cases treated with this agent being only 25 per cent.

New Sponges from the Puerto Rican Deep

DR. M. W. DE LAUBENFELS has described twenty-seven new species of sponges from the Puerto Rican Deep (Johnson Fund. Reports on the Collections obtained by the First Johnson-Smithsonian Deep-Sea Expedition to the Puerto Rican Deep. Smithsonian Miscellaneous Collections, **91**, No. 17. Dec. 1934). Nearly one fourth of the total number of sponges collected by this expedition were new. Many of them may have been collected and described before, but unrecognisably, because in the descriptions made more than fifty years ago very little attention was paid to those microscopic characters that to-day are considered of primary importance. All the new species belong to the Demospongiæ, and these belong to 17 families, of which 4 are new, and 26 genera, of which 11 are new. Only a few species belonging to the Calcarea (or Calcispongiæ) and somewhat more of the Hexactinellida (or Hyalospongiæ) were found, and apparently no new species of either of these two orders. A final report is in progress which will include these.

Aphid Transmission of Strawberry 'Yellow-edge' Virus

The constant association of 'yellow-edge' disease of strawberries with the presence of the tarsonemid mite (*Tarsonemus fragariæ*) led to an investigation, by Mr. A. M. Massee, as to whether the mite was a vector of this particular virus disease (*J. Pomol. and Hort. Sci.*, **13**, No. 1, pp. 39–53, March 1935) which showed that this relation does not hold. The strawberry aphis (*Capitophorus fragariæ*), however, is proved to transmit the disease to healthy plants in the month of June, though there is some doubt about its ability to do so in late July and August. The tarsonemid mite causes severe damage on its own account, and frequently masks the appearance of virus symptoms.

Observations on *Sorghum*

Two short papers which have appeared in *Current Science* of February, 1935, describe "Bulbils in *Sorghum*" and "*Sclerospora* Sp. and Suppression of the Awn in *Sorghum*". The former article, by G. N. Rangaswami Ayyangar and V. Panduranga Rao, of the Millet Breeding Station, Coimbatore, India, announces the discovery of vegetative bulbils in place of grains in a small percentage of the progeny of a cross between single-seeded and double-seeded *Sorghum*. The second paper is by G. N. Rangaswami Ayyangar and P. V. Hariharan, and describes the symptoms of attack by a species of *Sclerospora* fungus. This has the effect, among other actions, of suppressing the awns of *Sorghum*. The leaf-blade is the most susceptible part of this plant in attack by *Sclerospora*, and as the awn has been considered homologous with the leaf blade, it seems natural that the awns should be suppressed, yet curious that organs of such divergent morphology should be attacked so specifically.

Petroleum Fuels in Canada

THE Mines Branch, Department of Mines, Canada, in co-operation with the Dominion Fuel Board, has recently issued Bulletin No. 759 on deliveries of fuel oil, kerosene, gasoline and petroleum coke in Canada during the last few years. In this statistical survey, fuel oil comprises all grades heavier than 42° A.P.I.; kerosene, the white and amber grades ranging from 42° to 47° A.P.I. plus distillate oils coming within these ranges; and gasoline those grades having 55° A.P.I. or lighter as their gravity. Statistics collected are presented in the form of eight tables showing gallons of the four classes of petroleum fuels marketed in Canada and their distribution in the provinces in 1932 and 1933; the amounts of fuel oil and kerosene delivered in the provinces and a classification of their specific uses; the sales of gasoline (and motor fuel) in Canada by provinces, and finally data of petroleum coke deliveries for domestic and industrial heating. Several interesting facts emerge from these statistics. In 1933, deliveries of petroleum products in Canada for fuel purposes amounted to 945 million Imperial gallons, of which 419 were fuel oil, 42 kerosene and 484 gasoline. Of the fuel oil delivered, 27 per cent was used for domestic heating, 21 per cent for industrial heating, 3½ per cent for tractor fuel and nearly 49 per cent for locomotive and bunker fuel. Of the kerosene delivered in 1933, representing approximately one twentieth of the aggregate of petroleum fuels, 54 per cent was accounted for by domestic heating, 37 per cent by tractor fuel and 9 per cent by general uses. As regards gasoline, statistics of sales show that in 1933 approximately 88 per cent was sold for motoring purposes and 12 per cent for other general uses.

Measurement of Solar Radiation

PROFESSIONAL Note No. 68 of the Meteorological Office, by Mr. H. L. Wright, contains comparisons between readings of the following instruments made at Kew Observatory in July–November 1927: (1) the Gorczynki pyrheliometer, (2) the Campbell-Stokes sunshine recorder, (3) the black bulb thermometer *in vacuo*. Of these three instruments, only the first represents a serious attempt to deal quantitatively with solar radiation; the second allows a rough estimate to be made of the length of time during which the radiation is above the minimum required to scorch the card of the recorder; the third purports to give a measure of the maximum intensity of the solar radiation each day by recording the highest temperature reached by a specially blackened maximum thermometer in a glass-walled chamber from which, as far as possible, all air is removed. Official meteorology, in Great Britain at least, has not of late taken the black bulb thermometer seriously, and the records of this instrument do not appear in the regular official publications. Among the comparisons is a diagram showing daily totals of radiation obtained with the pyrheliometer plotted against the estimated durations of bright sunshine given by the Campbell-Stokes instrument. This shows that the average daily rate at which radiation is received at a surface normal to the sun's rays at Kew under the best conditions is 0·95 gm. cal./cm.^{2} per minute, that is, about half the solar constant. The highest instantaneous rate was 1·43 gm./cal. on September 24, 1927, in polar air behind a depression over the North Sea, with the barometer down to 985 millibars and rising briskly. Comparisons between the widths of the burns on the cards of the sunshine recorder and the associated rates of radiation give an exponential relationship, the rate of radiation being proportional to e raised to the power $0{\cdot}64\ w$, where w is the width of the burn. The recorder was found to be insensitive to radiation of less than about 0·2 gm./cal. The figures relating radiation to the black bulb

readings are of interest mainly in that they show how well founded are the official objections to the latter instrument. It appears that the maximum rate of radiation for a given black bulb maximum is much less in July and August than in October and November.

A New Theory of Atmospheric Electricity

IN a long paper, published in the March issue of *Terrestrial Magnetism and Atmospheric Electricity*, Ross Gunn develops a new theory which claims to explain the generation of electric charges in clouds as well as many cognate phenomena. The theory depends on what its author calls "some preliminary and not very well-controlled experiments . . . devised and carried out as a result of certain theoretical considerations". A small 'pill-box' of thin sheet tin was connected to an electrometer. An iron disc was reduced to the temperature of carbon dioxide snow and quickly placed inside the pill-box. As the box cooled, water condensed on the outside and the box acquired a negative potential, about $-0{\cdot}1$ volt; then, as the pill-box warmed up, condensation ceased and after a minute or two the potential became positive. Gunn accepts the experiment as sufficient demonstration that condensation produces negative electrification of the water and positive electrification of the air, whilst evaporation produces positive electrification of the water and negative electrification of the air. Other investigators have looked in vain for such results of condensation and evaporation. Gunn assumes that these processes go on in the clouds and says that when raindrops are formed in an ascending current, the drops acquire negative charges whilst the positively charged air passes up to the top of the cloud. It may be remarked that the Ross Gunn cloud, like the Wilson, would have a positive charge above, and a negative charge below. Whether clouds of this type really predominate is a question which should have been settled long ago.

The Rectifier Photocell

A RECENT article by G. P. Barnard (*Proc. Phys. Soc.*, May) gives working details of the preparation of a new selenium-sulphur photo-cell of the 'Sperrschicht' type and an account of its properties. Photo-cells of this general type are obtainable commercially, but hitherto there has been no account sufficiently detailed to allow the construction of a cell for any special purpose. The cells were made by coating iron discs with the molten selenium-sulphur mixture, annealing, and sputtering lightly with gold, silver or platinum. The heat treatment of the films is critical; the active layer consists of selenium embedded in a matrix of sulphur-selenium eutectic in which the sulphur enters the selenium lattice. Theories of the behaviour of the cells have been given by A. H. Wilson and by Frenkel and Joffé. Both theories involve the assumption that in the system metal–semiconductor–metal there is a definite gap at one of the interfaces. The experimental behaviour of the cells is rather complicated because the illuminated cell behaves as a source of E.M.F. shunted by one resistance and placed in series with another. The behaviour varies, therefore, with the characteristics of the external circuit. It is expressed in the paper by sets of curves, and compared where possible with theory. The spectral sensitivities of some of the cells were measured.

Migration of Sodium on Tungsten

R. C. L. BOSWORTH (*Proc. Roy. Soc.*, A, May 1) has investigated the mobility of adsorbed sodium atoms. A patch of alkali atoms was sprayed on to a tungsten strip as positive ions from a Kunsman filament, and the movements of the sodium were followed by exploring the strip with a sharply defined spot of light and making use of the photo-electric effect of the sodium-covered surface. It was first found that an active patch decayed with time, apparently due to a migration of sodium into the intercrystalline cracks of the tungsten. The sodium could be partly recovered by heating the strip to 1,300° K., and, after about 10^{17} atoms had been deposited per sq. cm., the strip was saturated and the surface layer remained stable. When a patch had been obtained, it was found that it spread over the surface at an appreciable rate at room temperature and more rapidly at 800° K. At the latter temperature the strip is approximately uniformly active after 5–10 seconds. The temperature variation of the diffusion process is used to obtain an 'activation energy' for the migration process. The results are interpreted by supposing that a sodium atom may take up the activation energy of about 0·25 volt and pass into a mobile state in which it can migrate for considerable distances, either over the surface or into the cracks.

Stellar Motions

IN "A Preliminary Note concerning a New Theory of the Motions of the Stars" (*Proc. Nat. Acad. Sci.*, **21**, 143; 1935), J. Schilt describes what might better be called a new empirical analysis of these motions. He has first taken known rectangular velocity-components $\dot{X}$, $\dot{Y}$, $\dot{Z}$ of A-type stars, and chosen his $\dot{Z}$-direction in such a manner that *the density of velocity-points has maximum gradient in this direction*. He then fixes attention on the $\dot{Z}$-velocities, rather than on the velocity components in the preferential direction determined in the more usual way by use of the velocity-ellipsoid. The $\dot{Z}$-velocity component for any star is expressible in terms of the angle between the direction of the star and the Z-axis, and the observed values of its parallax π and of its radial and proper motions. Schilt finds that it can be represented statistically as the sum of one of two constant values, and an 'expansion' term proportional to the Z-co-ordinate. The resulting relation can be solved for π, thus giving a new expression which may be used to obtain statistical parallaxes of stars from a knowledge of their velocities. The author has verified that a formula of this type is successful in a large number of cases in giving parallaxes in agreement with trigonometric values. He claims that it makes it possible to gain insight into the 'giant' part of the Hertzsprung-Russell diagram, where spectroscopic and trigonometric parallaxes are not available. He further considers that his analysis gives a better account of the distribution of radial velocity than does the 'double wave' representation suggested by the theory of galactic rotation. However, from the theoretical, as opposed to the empirical, point of view, the work must ultimately be tested in the light of some very general considerations regarding the properties of arbitrary velocity distributions, which have lately been brought forward by E. A. Milne (see *Observatory*, **58**, 167, June 1935).

Geological Survey and Museum

CEREMONIAL OPENING OF NEW MUSEUM

ON Wednesday, July 3, H.R.H. The Duke of York performed the opening ceremony of the new Museum of Practical Geology in Exhibition Road, South Kensington. A description of the building and its principal exhibits appeared in NATURE of June 29 (p. 1060).

His Royal Highness was received at the door of the Museum by the Mayor of Kensington. The official party that accompanied the Duke to the platform were: The Right Hon. W. G. A. Ormsby-Gore, First Commissioner of H.M. Office of Works, Lord Rutherford, chairman of the Advisory Council for Scientific and Industrial Research, Sir Patrick Duff, secretary of H.M. Office of Works, Mr. J. H. Markham, the architect, Sir Frank Smith, secretary of the Department of Scientific and Industrial Research, Sir John Flett, the director of the Geological Survey, and Dr. W. F. P. McLintock, the curator of the Museum.

Mr. Ormsby-Gore, in inviting His Royal Highness to declare the Museum open to the public, said that the Geological Survey of Great Britain is the oldest national geological survey in the world. It was instituted for the purpose of preparing copies of the Ordnance Survey maps geologically coloured so as to be of service to science and industry by providing an accurate representation of the geology of Great Britain. The Museum of Practical Geology developed out of the collection by the Survey of specimens of rocks, minerals and fossils, and was first opened to the public in 1841. It was soon found that the importance of the collection warranted the erection of a building designed to display the work of the Survey and the application of geology to the arts and industry, and in the year of the Great Exhibition the building in Jermyn Street was opened by the Prince Consort. The new Museum was commenced in 1929 and was substantially completed in 1933, when it was required for the World Monetary and Economic Conference. The cost of the building was some £220,000, and a lease of the Crown site of the old premises had been granted at a rent which considerably exceeded the interest on the capital sum expended on the new building.

The Duke of York said that the new building makes a notable and welcome addition to the great museums erected on the land provided for the encouragement of science, art and industry by the wise foresight of the Prince Consort. With the Science Museum on one side and the natural history section of the British Museum on the other, it provides a suite of scientific exhibits unequalled in any other country. In 1683 the Duke of York, later James II, opened the Ashmolean Museum at Oxford, which contained the first British geological collection. In 1835, as a result of the work of Henry de la Beche, the Geological Survey was founded as the first official organisation of its kind. To-day there are more than 120 official geological surveys in different parts of the world, to many of which, and particularly those in other parts of the Empire, the Geological Survey of Great Britain has been a parent. He was glad to know that a large number of delegates from abroad had come to celebrate the centenary of the Survey.

The Museum was well filled with a large and representative gathering that included British, Colonial and foreign geologists who had been invited to participate in the ceremonies. The new Museum was much admired and it was generally acknowledged that no geological survey in the world has better offices, library and laboratories and a more satisfactory museum. Some of the directors of geological surveys took many notes of the organisation and arrangements of the exhibits, and they were particularly struck by the effort that has been made to attract the interest of the non-geological public.

On Wednesday evening, July 3, the Geological Society of London gave a reception to the foreign and Empire delegates in its rooms in Burlington House.

CENTENARY OF THE GEOLOGICAL SURVEY

On Thursday, July 4, at 11 a.m., a meeting was held in the hall of the Royal Geographical Society to celebrate the centenary of the Geological Survey of Great Britain. Lord Rutherford of Nelson occupied the chair, and was accompanied by Sir Frank Smith and Dr. T. F. Sibly, representing the Department of Scientific and Industrial Research and the Geological Survey Board.

In a brief introductory speech, Lord Rutherford commented on the great progress which the knowledge of geology has made in the last hundred years and the distinguished part which British geologists have played in furthering the growth of the science. He cited the names of William Smith, Lyell, Sedgwick, Murchison, Darwin and others as founders of geology, and expressed his thanks to the foreign, Dominion and Colonial geologists who had accepted the invitation to assist in the celebration.

The overseas and British delegates then responded to their names and were presented to the chairman.

The list of delegates is much too long to be given in full as it contains more than two hundred names, of which 85 were from foreign countries. Mention, however, may be made of a few selected names. The Belgian delegation was very representative, including Prof. Renier (Brussels), Prof. Fourmarier (Liège), Profs. Halet, Legraye, Van Straelen and Thoreau. Prof. Robert represented the Geological Survey of the Belgian Congo. From France arrived Profs. de Margerie, Jacob (Paris), Léon Bertrand (Paris), Fallot (Nancy), Dubois (Strasburg), Roman (Lyon), Besairie (Madagascar), Bétier (Algeria), Legoux (French West Africa). The German delegation was led by Prof. von Seidlitz (Director, Geological Survey of Prussia) and included Profs. Stille, Cloos, Hirmer, Angenheister and Schmidtgen. Among others present were Madsen (Denmark), Gavelin and von Eckermann (Stockholm), Laitakari (Helsingfors), Kettner (Prague), Crema (Italy), Loczy de Locz (Hungary), Morozewicz (Poland), Royo y Gomez (Madrid). The Swiss representatives were Profs. Lugeon, Buxtorf and Staub, and much interest was taken in the two Russian delegates, Prof. Ferodowsky (Moscow) and Prof. Karpinsky, the president of the

Academy of Sciences in Leningrad, who is in his ninetieth year and had flown to London, accompanied by his daughter. From the United States there came Dr. Day of the Geophysical Laboratory of the Carnegie Institution of Washington; Dr. Matthews, Johns Hopkins University, Baltimore; Profs. Rice (Harvard), Moore (Kansas), Marquis (Washington), Leith (Wisconsin), Anderson (Stanford), Leuschner (Berkeley). From Canada, Profs. Coleman (Toronto), Adams (Montreal), Atkinson (Saskatoon). Among other distinguished Empire geologists present were Grabham (Sudan), Haughton (Pretoria), Richards (Queensland), Kitson (Victoria), Pascoe (India), Lightfoot (Southern Rhodesia), Seymour (Dublin), Mellor (Johannesburg), Scrivenor (Malaya) and Raeburn (Nigeria).

Thereafter, Sir John Flett, director of the Geological Survey and Museum, gave an address on the history and functions of the Geological Survey. He outlined briefly the state of geological science in the year 1835 when the Survey was founded, and remarked on the brilliant assemblage of geologists then living in London, among whom were Buckland, Murchison, Sedgwick, Lyell, Greenough, Fitton, MacCulloch and De la Beche. Much interest was being taken in geological maps. William Smith's famous map had appeared in 1815. Greenough's map was issued in 1820. A desire for still better maps was strongly felt and with the support of Colby, director of the Ordnance Survey, a deputation of prominent members of the Geological Society of London represented to the Prime Minister the value of geologically coloured maps on the scale of one-inch to a mile. Consent was obtained and the work was entrusted to Henry de la Beche. The work began in Devon and Cornwall, spread thence to Wales and eastwards to the London district and the Midlands. By 1860 it had reached the Lancashire and Yorkshire coalfields, and in 1883 the original survey of England and Wales was finished. Simultaneously, the Geological Surveys of Ireland and Scotland had been active both in field work and in publication. De la Beche was remarkably successful in enlisting able and enthusiastic assistants, among whom Ramsay, Aveline, Selwyn, Logan and Jukes did imperishable work.

De la Beche died in 1855 and was succeeded by Sir Roderick Murchison, who was an active and efficient director. He was followed by Sir Andrew Ramsay, equally skilled in the field and with the pen, who had been De la Beche's loyal lieutenant. Sir Archibald Geikie in turn held control until the end of last century. What is known as the 'Old Series' of hand-coloured geological maps was essentially the product of the labours of the staff under these leaders. In 1901 Sir Jethro Teall took up the reins, followed by Sir Aubrey Strahan. Many improvements were made in all departments of the service and the present type of colour-printed maps was introduced.

At first under the Board of Ordnance, then under the Woods, Works and Forests, then under the Board of Trade and the Science and Art Department, soon transferred to the Board of Education, and since 1919 under the newly constituted Department of Scientific and Industrial Research, the Geological Survey and Museum has pursued an even course.

De la Beche started to exhibit geological specimens, maps, models and mining apparatus in rooms in Craig's Court about 1837. The old Museum of Practical Geology in Jermyn Street was opened by the Prince Consort in 1851. It is now in process of demolition. This furnished an opportunity to realise De la Beche's ambition to found a School of Mines resembling the famous institutions of the Continent, and in this also he was successful. After preliminary vicissitudes the School achieved a great reputation and many famous names are found in the lists of its staff. Forbes, Huxley, Playfair, Frankland, Warington Smyth, Percy, Stokes, Tyndall, Le Neve Foster, were among the professors. The men who were privileged to study under them are justly proud of their School and its great traditions.

The School of Mines outgrew its accommodation at Jermyn Street and was transferred by stages to South Kensington, where now it occupies commodious buildings adjacent to the Science Museum and the Geological Survey and Museum.

The practical applications of geology were never absent from the mind of De la Beche. He established a Mining Record Office for collecting statistics of output and plans of mines. His chemists also attacked many practical problems, such as British iron ores and steam coals for the Navy. Science was for him not a lonely virgin but the fruitful partner of industry. Could he return to-day and see how widely his influence has spread, even he might be astonished. The old collections of Jermyn Street have fertilised the Science Museum, Bethnal Green Museum, Science Library, School of Mines, Mines Department, Imperial College and the Victoria and Albert Museum. All of these contain material that can be traced to his assiduous and enterprising activities. His successors, though their energies are less widely dispersed, maintain close connexion with practical problems. Water-supply, engineering, fuel research, agriculture, mining, architecture, transport, all call for geological information and receive their due share of attention.

At the conclusion of the director's address, the chairman called upon some of the delegates to speak. Prof. Coleman (Toronto), Prof. Matthews (Baltimore), Prof. de Margerie (Paris), Prof. von Seidlitz (Berlin) and Prof. W. W. Watts (London) in turn expressed their appreciation of the work of the Geological Survey, and the services it has rendered to geological science and to the prosperity of Great Britain.

In the evening at 7 o'clock the staff of the Geological Survey and the members of the Dining Club of the Geological Society entertained the Overseas delegates and their wives to dinner at the Rembrandt Hotel. The Company numbered 220 and only two speeches were delivered. Sir John Flett as chairman proposed the toast of the guests, which was responded to by Dr. A. L. Day, director of the Geophysical Laboratory of the Carnegie Institution of Washington and vice-president of the National Academy of Sciences of the United States.

Thereafter the company proceeded to Lancaster House, where a Government reception was held. The guests, numbering more than a thousand, were received by the First Commissioner of H.M. Office of Works and Lady Beatrice Ormsby-Gore.

On Friday, July 5, a series of excursions to districts of geological interest, specially conducted by officers of the Geological Survey for the benefit of those who attended the celebrations, left London. The selected localities are Edinburgh and the Forth Valley, Bristol and South Wales, and the Isle of Wight. Each excursion is to last for a week, and descriptive programmes and itineraries have been specially prepared.

Hydraulic Couplings and Torque Converters

IT is indicative of the interest being taken by engineers in the comparatively recent hydraulic method of transmitting torque and to the importance attached to its development that three papers on this subject were read during April and May before the Institution of Mechanical Engineers. Its application, as the fluid flywheel, to automobile drives has attracted to it the attention of a much wider public than the engineering profession.

Some misconception is prevalent regarding this method of transmission. While it is rightly understood that power is transmitted from one disc—the 'driver' or 'impeller'—to another quite unconnected disc—the 'runner'—by the action of the oil which is kept in circulation, it is assumed by many that the oil is enabled to do this by acquiring some quality of lateral resistance due to an extraordinary degree either of shear resistance or of viscosity imparted to it by the circulatory velocity. In fact, however, the explanation is much simpler. The 'impeller' disc acts on the oil as a centrifugal pump imparting kinetic energy to it, and discharges it into the 'runner' disc, which operates as a turbine and receives energy from the liquid. Its discharge goes back to the impeller for the next cycle of energy transfer.

In his paper "Recent Developments in Hydraulic Couplings" (*Proc. Inst. Mech. Eng.*, April 26) Mr. Harold Sinclair explains the fundamental differences between the two systems of hydraulic transmission—the displacement or hydro-static system and the turbo or hydro-kinetic system, to which latter these couplings and converters belong—and the main advantages of the turbo system. Following a brief historical survey from the pre-War speed transformers originated by Dr. Föttinger for marine turbine propulsion, he outlines the elements of the theory on which this type is based. Proceeding mainly in a descriptive and explanatory vein, the author devotes the bulk of his paper to the development of the Vulcan-Sinclair Coupling. This is a modification of the Vulcan marine type to meet the conditions of industrial and automotive service, and particulars are given of its application in three distinct forms: (1) the scoop type for constant speed motors driving variable speed machines, (2) the traction type, including the fluid flywheel, for variable speed engines and motors, and (3) the ring valve traction type for both constant and variable speed engines.

In "Voith Turbo Transmissions" (*Proc. Inst. Mech. Eng.*, May 3) Dr.-Ing. Wilhelm Hahn discusses the application of torque converters and hydraulic couplings. The former, having in addition to the two discs—the 'impeller' and the 'runner'—a stationary guide ring, is enabled to step up the value of the torque and so is capable of overcoming a high starting resistance. After examining theoretically the relationship between power, torque and speed in a torque converter and considering the conditions for maximum efficiency, he suggests that, to attain as nearly as possible to the ideal torque curve, the torque converter be used for starting up and that, at the appropriate moment, a change-over be effected to the direct drive of a hydraulic coupling.

The necessity for this change-over and the duplication it involves arises from the practical difficulty of fitting the converter with variable blades on the stationary ring so that it is adaptable to all conditions. In "Progress in Design and Application of the Lysholm-Smith Torque Converter" (*Proc. Inst. Mech. Eng.*, May 3), Messrs. Haworth and Lysholm discuss the theory of blade friction and the results of experiments. The main points to be provided for in design are set forth and the results of experiments showing the effects of various blade angles and wheel diameters are given, together with the results of several applications, including a 1,000 h.p. variable blade converter.

Taken together, the three papers give a very good picture of the present position in this practically new method of fluid transmission.

The National Museum of Natural History, Paris

THE National Museum of Natural History, Paris, which was founded by Guy de la Brosse in May 1635 on the site of the Jardin des Plantes—"Le Jardin du Roy"—by an edict of Louis XIII, celebrated its tercentenary in Paris during the last week of June. The celebrations commenced on June 21 with a reception of the delegates by the director and the professors of the Museum, but the most impressive part of the various ceremonies was the *séance solennelle*, which was held in a special marquee erected in the Jardin des Plantes on the afternoon of June 25. This ceremony was attended by about 570 French and foreign delegates, representing 35 academies, 71 universities, 117 scientific institutions and 110 scientific societies, and was honoured by the presence of M. Albert Lebrun, the President of the Republic. The Minister of Education, M. Mario Roustan, presided, and the delegates presented their addresses at the commencement of the *séance*.

Speeches were made by M. Paul Lemoine, director of the Muséum National d'Histoire Naturelle; by the Governor-General, M. Olivier (president of the Society of Friends of the Museum); by M. Alfred Lacroix (member of the Institute and professor at the Natural History Museum), speaking in the name of the Academies; by M. M. Caullery (member of the Institute and professor at the Sorbonne), in the name of the French delegates; and by Sir Arthur Hill (director of the Royal Botanic Gardens, Kew),

in the name of the foreign delegates. The proceedings concluded with a speech by M. Mario Roustan, the Minister of Education.

Sir Arthur Hill, after referring to some of the distinguished botanists who had made the name of the Museum famous throughout the world, concluded a noteworthy speech, which brought the whole company to their feet, with the following words:

"Tous ceux-ci—et beaucoup d'autres—ont fait rayonner leur lumière sur le monde entier, au travers de ce Temple Renommé, le Musée National d'Histoire Naturelle.

"M. le Président, permettez à un botaniste de vous rappeler la fameuse parole de votre grand philosophe Pascal: L'homme fut perdu et trouvé dans un Jardin. Dans le premier jardin, le Jardin d'Eden, l'homme ouvrit la porte de la Science en mangeant le fruit de l'arbre de la connaissance du Bien et du Mal. Pouvons nous exprimer l'espoir que, non-seulement en France, mais au travers du monde entier, malgré les temps si troublés que nous traversons, unis dans un même idéal de tolérance et d'harmonie, les chercheurs de la Vérité verront leurs efforts récompensés par la découverte de cet autre arbre—'L'Arbre de Vie', dont les feuilles nous assureront la Paix eternelle, parmi les Nations?

"M. le Président, je prie mes collègues Délégués de se joindre à moi, et, debouts, de rendre hommage à la mémoire de ceux qui ont fait le nom de ce Musée si grand, et d'offrir avec moi nos meilleurs vœux pour la continuité de la prosperité et la gloire du Musée National d'Histoire Naturelle."

In the evening there was an official banquet attended by some seven hundred guests, and the Earl of Crawford spoke on behalf of the British delegates.

Another event of the week was the opening of the Grande Galerie de Botanique du Jardin des Plantes, the erection of which was assisted by a grant from the Rockefeller Foundation. This magnificent new building consists chiefly of the herbarium, which is one of the largest in the world. The building is fire-proof and the herbarium cabinets are constructed of metal. There is very limited table space, and most of the research work is carried out in the adjoining private rooms and laboratories, several of which have been set aside for the use of visitors. There is, moreover, particularly good accommodation for workers on the lower cryptogams, some seven rooms being set aside for algology, and an equal or larger number for mycology. Including more or less loosely attached workers, there is a large staff, but the new herbarium laboratories are also used by university students in connexion with research for degree theses.

Visits were paid to the Château of Chantilly and various museums, as well as to the zoological parks at Clères and Vincennes and the experimental grounds and laboratories of M. Vilmorin. The celebrations in Paris were very pleasantly brought to a close by a garden party at the Élysée, when the President of the Republic and Mme. Lebrun received the delegates.

At the end of the festivities an excursion was made to Mont Saint-Michel, Saint-Malo and Dinard, and at Dinard the new museum and aquarium, recently completed, was formally opened in the presence of a large number of the delegates.

Thanks to M. Lemoine, the director of the Museum, to Dr. Jeannel, who was acting as secretary, and his assistants, the arrangements for the celebrations were admirably carried out.

A very interesting exhibition of portraits of all the distinguished botanists, zoologists and others connected with the Museum, together with a fine collection of old prints and pictures and many other objects connected with the history of the Museum, had been arranged in the Exhibition Hall of the recently completed herbarium and botanical laboratories referred to above.

Academies, universities and scientific institutions from all over the world sent delegates to the celebrations. The following institutions, among others, of Great Britain, were represented: Royal Society (Earl of Crawford and Balcarres and Dr. C. Tate Regan); British Museum, Natural History (Earl of Crawford and Balcarres, Dr. C. Tate Regan and Mr. J. Ramsbottom); Royal Botanic Gardens, Kew (Sir Arthur Hill and Mr. A. D. Cotton); British Association (Mr. J. Ramsbottom); and the Linnean Society of London (Mr. J. Ramsbottom and Prof. G. D. Hale Carpenter).

Biological Distribution of Molybdenum

PROF. H. TER MEULEN, of Delft, continues his studies on the distribution of molybdenum in the organic world, with the help of Miss H. J. Ravenswaay (*K. Akad. Wet. Amsterdam, Proc.*, **38**, i; 1935; see also NATURE, **130**, 966; 1932). Finding in various samples of Dutch East Indian tobacco no less than 0·5–0·7 mgm. of molybdenum per kgm., he went on to determine the molybdenum content of the soil in a number of tobacco plantations. In some the amount was small, 0·01–0·07 mgm. per kgm.; in others it was ten times as much, 0·12–0·3 mgm.; and the latter were always the best plantations, growing the best tobacco.

Next, Prof. Ter Meulen extended some former studies of the seasonal variation of molybdenum in leaves; he finds in about a dozen different trees that the amount per kilogram, or per 1,000 leaves, either remains constant or sometimes increases considerably, from the young leaves of spring until the autumn leaves are about to fall. In other words, the molybdenum does not migrate from the old leaves to the other tissues of the plants, but merely returns with the fallen leaves to the soil. The horse-chestnut is an exception; here the amount of molybdenum in the leaves decreases in September and still more in October. But the horse-chestnuts themselves contain this element in considerable amount, and have, in all probability, withdrawn it from the leaves.

A third interesting point is a comparison of the molybdenum content in the brown and green varieties of *Prunus*, hazel and beech. Leaves were plucked on the same day, and the molybdenum estimated in mgm. per kgm. of moisture-free material. The curious and striking result was that in all three species the brown-leaved varieties were found to contain about twice as much molybdenum in their foliage as the green ones.

Still more recently, Prof. Ter Meulen has studied the molybdenum content of human teeth, sound and carious, and finds the sound teeth to be very much richer in molybdenum than the unsound. In all these cases it seems natural to suppose that the molybdenum is playing its part as a catalyst, and as such it would seem to be of widespread use and importance.

Educational Topics and Events

CAMBRIDGE.—The Vice-Chancellor announces that he has received a letter from Sir John D. Siddeley offering to the University the sum of £10,000, spread over a period of seven years, to help the development of aeronautical research and to assist the work of Prof. Melvill Jones and his associates in the Sub-Department of Aeronautics in the University. No specific conditions are attached to the offer, but Sir John Siddeley suggests that it may be found best to allow a considerable proportion to accumulate to form a capital endowment and to use the remainder for immediate purposes.

The Harkness Scholarship for 1935 has been awarded to Miss D. H. Rayner, of Girton College.

The Frank Smart Prizes are awarded to M. F. Mare of Newnham College (Botany) and D. W. Ewer, of Trinity College, and R. S. Sturdy, of Trinity College (Zoology and Comparative Anatomy).

LONDON.—University Postgraduate Travelling Studentships of the value of £275 for one year have been awarded to R. G. R. Bacon (Imperial College—Royal College of Science) and to A. E. J. Went (Imperial College—Royal College of Science). Mr. Bacon proposes to carry out chemical research in the University of Zurich, and Mr. Went will study the ecology of the mackerel in Norway.

The University Studentship in Physiology of the value of £100 has been awarded to R. A. Gregory (University College), who will carry on physiological research at University College.

OXFORD.—Lord Nuffield has given £16,000 for the purposes of the new institute for medical research. This is additional to the Radcliffe Observatory buildings and their surrounding land, which he bought when it was proposed to remove the observatory to South Africa. The institute is now to be called the Nuffield Institute for Medical Research.

In 1936 the Halley Lecture is to be delivered by Prof. P. M. S. Blackett and the Herbert Spencer Lecture by Emeritus Prof. J. A. Smith.

The Osler Memorial Medal for 1935, for the most valuable contribution to the science, art or literature of medicine made by an Oxford medical graduate, has been awarded to Dr. A. F. Hurst of Magdalen College.

SHEFFIELD.—The following appointments have recently been made: Dr. Francis Davies, reader in anatomy in King's College, University of London, to be professor of anatomy, in succession to Prof. C. J. Patten, who is retiring; Mr. R. T. Percival, to be lecturer in metallurgy (founding); Mr. John S. Bennett, to be assistant lecturer in metallurgy (founding).

THE following studentships and scholarships for 1935 have been awarded by the Royal Commission for the Exhibition of 1851, the name of the recommending university or college being given in brackets: *Senior Studentships*. Dr. Dorothy Hill (Cambridge), for research in geology at the University of Cambridge; S. F. Boys (Imperial College of Science and Technology, London), for research in physical chemistry at the University of Cambridge; Dr. H. Dickson (Imperial College of Science and Technology, London), for research in botany at the Imperial College; Dr. J. Walker (St. Andrews), for research in organic chemistry at the University of Oxford; Dr. W. C. Price (University College, Swansea), for research in physics at the University of Cambridge. *Overseas Scholarships*. R. C. Rose (Alberta), for research in physical chemistry at University College, London; Dr. A. B. Van Cleave (McGill), for research in physical chemistry at the University of Cambridge; J. S. Marshall (Queen's University, Kingston), for research in physics at the University of Cambridge; A. M. Crooker (Toronto), for research in physics at the University of Cambridge or the Imperial College of Science and Technology, London; J. R. Price (Adelaide), for research in organic chemistry at the University of Oxford; J. C. Bower (Melbourne), for research in physics at the University of Cambridge; J. W. Mitchell (New Zealand), for research in physical chemistry at the University of Oxford or King's College, London; Dr. H. A. Shapiro (Cape Town), for research in physiology at the University of Edinburgh. A number of senior studentships and overseas scholarships have been renewed for further periods.

Science News a Century Ago

European Aeronautical Society

UNDER the above heading, in *The Times* for July 14, 1835, was the following advertisement: "First Aerial Ship, the Eagle, 160 feet long, 50 feet high, 40 feet wide, manned by a crew of 17; constructed for establishing direct communication between the several capitals of Europe. The first experiment of this new system of aerial navigation will be made from London to Paris, and back again. May be viewed from 6 in the morning till dusk, in the dock-yard of the Society, at the entrance of Kensington, Victoria-road, facing Kensington Gardens, near the first turnpike from Hyde-park-corner. Admittance every day of the week 1s.; children half price."

A sketch and description of the airship appeared in the *Mechanics' Magazine* of July 18, 1835. The balloon or gas holder, it was said, was composed of 2,400 yards of cotton lawn, thoroughly varnished, and contained 7,000 cub. ft. of gas. The car was 75 ft. long and from it were worked the wings with which the machine was to be propelled.

The Scientific Association of Germany

IN its "Weekly Gossip on Literature and Art", the *Athenaeum* of July 18, 1835, said: "The Annual Meeting of the Scientific Association of Germany is to be held this year at Bonn on the Rhine, from the 17th to the 27th of Sept. At the meeting last year at Stuttgart, Dr. Christian Frederick Harless, Privy Councillor of Prussia and Professor of Medicine in the University of Bonn, and Dr. Jacob Noeggerath, one of the Directors in Chief of the Council of Mines for the Rhenish Provinces of Prussia, were respectively chosen President and Secretary of the ensuing meeting.

"The Geological Society of France meets in the beginning of September at Mezières and after examining the country there and around Namur, Liège and Aix-la-Chapelle joins the German Association at Bonn.

"There will be sufficient time to go to Bonn after the meeting of the British Association in Dublin, and we hope that our country will be worthily represented. . . . We know that, in the true spirit of German hospitality the Committee are anxious to provide

comfortable quarters for all strangers; but the town is small, and therefore they should get as early advise as possible. Letters should be addressed to Prof. Noeggerath."

The German Association was formed some years before the British Association, and Brewster, writing to Phillips on February 22, 1831, said: "It is proposed to establish a British Association of men of science similar to that which has existed for eight years in Germany, and which is now patronized by the most powerful sovereigns of that part of Europe."

Darwin in Peru

ON July 19, 1835, Darwin records that the *Beagle* anchored in the Bay of Callao, the seaport of Lima, the capital of Peru. Callao he found 'a filthy, ill-built, small seaport', while, owing to the troubled state of affairs, he was able to see little of the country. "I cannot say," he wrote, "I liked the very little I saw of Peru; in summer, however, it is said that the climate is much pleasanter. In all seasons, both inhabitants and foreigners suffer from severe attacks of ague. This disease is common on the whole coast of Peru, but is unknown in the interior. The attacks of illness which arise from miasma never fail to appear most mysterious. So difficult is it to judge from the aspect of a country, whether or not it is healthy, that if a person had been told to choose within the tropics a situation appearing favourable for health, very probably he would have named this coast. The plain round the outskirts of Callao is sparingly covered with a coarse grass, and in some parts there are a few stagnant, though very small, pools of water. The miasma, in all probability, arises from these: for the town of Arica was similarly circumstanced, and its healthiness was much improved by the drainage of some little pools. . . . In all unhealthy countries the greatest risk is run by sleeping on shore. Is this owing to the state of the body during sleep, or to a greater abundance of miasma at such times?"

Faraday on Tour in Switzerland

THE year 1835 was not one of Faraday's periods of great activity. It was in fact a time of rest and recuperation between the electrochemical researches, which were completed, and those on electrostatics, which he began to think of in November 1835. There is no entry of any kind in his Diary after April 27 until August, and in the month of July he was on a holiday tour in Switzerland with his wife and brother-in-law, George Barnard. The need for relaxation after a long period of hard work had evidently been felt, for in a letter he wrote to Magrath from Switzerland on July 19, he speaks of "occupation, fatigue and rheumatism". In the same letter he says: "We had a rough passage to Dieppe from Brighton, so rough that we found the French people wondering that we had ventured, but were so unhappy in our sickness as to be quite unconscious of everything else".

The party travelled by Rouen and Paris to Geneva, where Faraday met Prof. De la Rive again, and then to Chamonix and on for a tour of the mountain scenery. "We are almost surfeited with magnificent scenery", he wrote to Magrath; and again: "No artist should try to paint Mont Blanc; it is utterly out of his reach. He cannot convey an idea of it". They were back in England in August, for on August 6 the Diary entries begin again.

Societies and Academies

DUBLIN

Royal Irish Academy, June 25. H. L. MOVIUS, JR.: An excavation in the diatomaceous deposit of the Lower Bann Valley. The site, which was excavated in June 1934 by the Harvard Archæological Expedition to Ireland, lay at the base of an extensive deposit of diatomite where some thirty hearths were discovered. Implements of flint in addition to three polished stone axes were found. Typical of the industry are pointed flakes with a superficial tanging of the bulbar end. The site never served as a place of permanent habitation, since the hearths show evidence of seasonal floodings by the river. A nearly complete pot from quite near the site has proved to belong to the Windmill Hill family of Neolithic ware, according to Prof. V. G. Childe. The archæological evidence points to about the beginning of the second millennium B.C. as a rough date for the culture. Such a view is substantiated by Prof. K. Jessen's palæobotanical studies at the site, and on the basis of his work Late Atlantic to Early Sub-Boreal time is probable. As a whole, the industry seems to be an indigenous North Irish development derived from earlier coastal elements which had come in contact with a fully developed neolithic civilisation.

PARIS

Academy of Sciences, May 27 (*C.R.*, 200, 1805–1892). The president announced the death of Hugo de Vries, *Correspondant* of the Academy. ARMAND DE GRAMONT: An optical inverter. CHARLES CAMICHEL, JEAN PARMENTIER and LOUIS ESCANDE: Contribution to the study of liquid veins: multiple solutions: non-commutative operations. Experiments carried out on reduced models and on the Vives-Eaux barrage on the Seine. RENÉ MAIRE and LOUIS EMBERGER: The vegetation of the western Anti-Atlas. MARC KRASNER: The theory of the ramification of ideals. EMILE VAULOT: The application of the calculus of probabilities to the theory of telephone traffic. P. J. MYRBERG: The determination of the type of a simply connex Riemann surface. PIERRE BOOS: The general integral of certain differential equations considered as a function of the constants of integration. CARLO MIRANDA: A new criterion of normality for families of holomorph functions. NIKOLA OBRECHKOFF: The summation of the ultra-spherical series by the method of arithmetical means. GEORGES VALIRON: A generalisation of Schottky's theorem. EUGÈNE BLANC: Monotone multiform correspondences. GÉRARD PETIAU: A form of the equation of the photon. JULIEN KRAVTCHENKO: The validity of solutions of the problem of [ships'] wakes. F. CHARRON: Various utilisations of the bifilar suspension. L. DUNOYER: The principal cause of the inferiority of spirit-levels compared with liquid baths. JEAN P. E. DUCLAUX: The influence of light on the anodic polarisation of tungsten. ROBERT GUILLIEN: The electrical double refraction of liquid oxygen and nitrogen. MME. IRÈNE CURIE, HANS VON HALBAN, JR. and PIERRE PREISWERK: The artificial creation of the elements of an unknown radioactive family, during the irradiation of thorium by neutrons. MLLE. H. ZAVIZZIANO: The co-precipitation of protactinium with titanium. Titanium dioxide, formed by the hydrolysis of titanium

sulphate solutions, carries with it the whole of the protactinium in solution, and is better adapted for this purpose than the substances hitherto employed. VICTOR LOMBARD and CHARLES EICHNER: The large and sudden variation in the permeability of palladium to hydrogen at a temperature just below 200° C. Palladium foil loses 99·95 per cent of its diffusive power to hydrogen by cooling from 225° C. to 125° C. The critical temperature, which varies slightly with the purity of the metal, is between 180° C. and 190° C. The author regards this not as being due to a change of state of the metal but as a change of behaviour of hydrogen towards the palladium. MLLE. NIUTA KLEIN: Study of the inequalities of the index of refraction of a glass. ELIE RAYMOND: A method for the quantitative separation of nickel and cobalt. ANDRÉ DE PASSILLÉ: The thermochemistry of the ammonium arsenates. PIERRE BRAUMAN: The isoamyloxyvanadylsalicylates. ALFRED MAILLARD: The hydrogenation of anthracene. The addition of hydrogen to anthracene is a reaction similar to the hydrogenation of naphthalene; the addition takes place in stages and the reactions are reversible. E. VELLINGER and G. RADULESCO: The use of cracked spirit in internal combustion motors. The unsaturated hydrocarbons are valuable in preventing knocking, but the tendency to gum formation is objectionable. The latter can be removed by adding stabilisers such as polyphenols: that this addition prevents gum formation has been confirmed by experiment. GEORGES DUPONT and RAYMOND DULOU: The presence of active secondary butyl alcohol in certain fusel oils. A sample of propyl alcohol, sold as pure, was found to contain 17 per cent of active secondary butyl alcohol. JEAN WYART: The crystalline structure of paratoluidine. STOYAN PAVLOVITCH: The petrographical study of the peridotites of the Zlatibor massif (Western Serbia). GILBERT MATHIEU: The age of the primary series without fossils of Vendée. JEAN MICHEL: Observations on the projections in the chalk between Tréport and Ault. ADOLPHE LEPAPE and GEORGES COLANGE: The composition of the air of the stratosphere. The air of the stratosphere has the same composition as at the ground-level and it would appear that the atmosphere has sensibly the same composition throughout. L. DONCIEUX and J. CUVILLIER: The Foraminifera of the lower Lutetian in the south of the Arabian desert. GEORGES ADAM NADSON: Hereditary variations produced experimentally in yeasts. Starting with a single yeast cell, under the influence of the X-rays various new stable strains of yeasts have been obtained. These yeasts are so distinct that, if found in Nature, they would be classified not only as different species, but even as distinct genera. The distinctive characters have been maintained after several years of culture. EMILE MIÈGE: The indigenous cultivation of the potato in the mountainous regions of Morocco. The potato has been cultivated for a long period in the mountain regions of Morocco. In spite of the primitive methods, two crops a year with high yields without degeneration have been obtained. These results show the favourable effect of cultivation at a high altitude. LÉON BERTIN: The *Oxystomus* of Rafinesque is a distinct form among the leptocephalian larvæ. ALPHONSE LABBÉ: The silicogen function in the Silicoderms. JAMES BASSET, STEFAN NICOLAU and MICHEL A. MACHEBŒUF: The action of ultra-pressure on the pathogenic action of some viruses. JACQUES PARROD: The formation of hydrocyanic acid and urea by the oxidation of cellulose, in ammoniacal solution, at laboratory temperature. MLLE. HÉLÈNE WINOGRADSKY: The nitrifying micro-flora of activated sludge of Paris. E. GRASSET: Preliminary results on the treatment of human tuberculosis by means of living formolised lysates of B.C.G. and tuberculous bacillus.

BRUSSELS

Royal Academy (*Bull. Classe Sci.*, **31**, No. 4, April 6). L. GODEAUX: (1) Researches on the cyclic involutions belonging to an algebraic surface. (2) The order of the rational correspondences between two surfaces each of genus one. TH. DE DONDER: Application of quantum mechanics to generalised statistical mechanics. L. HENRIOT: Electromagnetic moments. A discussion of the vectors torque and momentor in Lorentz's electromagnetic theory and a comparison with the results of Maxwell's theory. G. BOULIGAND: On certain linear classes of functions. M. WINANTS: Solution of the problem (a_0, IV, 1). J. GÉHÉNIAU: Generalisation of the formulæ of excess of Weierstrass deduced from the theorem of independence of Hilbert – De Donder. YVONNE DUPONT: De Donder's thermodynamic synthesis applied to the Nernst and Ettingshausen transverse effects (2). GEORGETTE SCHOULS: Application of statistical mechanics to the thermodynamics of a gas. Theoretical considerations leading to a calculation of the molar entropies of chlorine, bromine and iodine, allowing for the energy of vibration. J. M. DELFOSSE and R. GOOVAERTS: Raman spectrum of silicobromoform. Comparison of the Raman effect in silicobromoform with that in chloroform, bromoform and silicochloroform. H. WUYTS and R. VERSTRAETEN: Optical analysis and rotatory power of the glycothiodiazolines. M. FLORKIN: Influence of the cryoscopic depression of the exterior medium on that of the blood and urine of *Anodonta*. B. ROSEN and M. DÉSIRANT: Researches on the molecular spectrum of selenium vapour. H. SAUVENIER: Some remarks on the subject of the interpretation of the shift towards the red of the spectral lines of nebulæ. M. NICOLET: Identification of the lines of neon in the spectrum of *B* stars. M. LEGRAYE: Note on a particular fuel in the Fammenian of the Couthuin region. J. MELON: Analysis and optical properties of thoreaulite.

GENEVA

Society of Physics and Natural History, May 16. M. GYSIN: Copper minerals of Kinsenda (Belgian Congo) (2). Presence of two varieties of chalcosine. Studying the minerals of Kinsenda (Belgian Congo), the author has observed two varieties of chalcosine, a blue chalcosine, isotropic, formed by hypogene replacement of primary bornite, and a white chalcosine, granular, anisotropic, formed by supergene replacement of blue chalcosine and of chalcopyrite. E. BRINER and M. CARCELLER: Catalytic action of oxidation exercised by ozone in the oxidation of hydrocarbons. E. CHERBULIEZ and R. WEIBEL: Action of sulphur on water below 100° C. and the geological significance of this reaction. P. WENGER, C. CIMMERMANN and C. RZYMOWSKA: The gravimetric micro-estimation of potassium in the presence of sodium by means of chlorplatinic acid. The authors specify the conditions of F. Emich's micromethod for the determination of potassium in the presence of ten times the quantity of sodium, and have

established a micromethod based on the work of Smith and Gring. C. CIMMERMANN and P. WENGER: The micro-estimation of zinc by means of anthranilic acid. The authors have worked out a rapid and exact micromethod based on the use of this reagent.

LENINGRAD

Academy of Sciences (*C.R.*, 2, No. 1, 1935). I. VINOGRADW: On approximation by means of rational fractions having powers of total numbers for denominators. V. IGNATOVSKIJ: The Laplacean transformation. L. RADZISHEVSKIJ: Contribution to a general theory of linear functional equations. V. KUPRADZE: A generalised 'principle of radiation' in the theory of elasticity. L. LEIBENSON: (1) The theory of the turbulent boundary layer. (2) The energy form of the integral condition in the theory of the boundary layer. A. MITKEVITCH: The influence of mechanical vibration on the subsequent manifestations of magnetic viscosity. V. IPATJEV and W. TRONEV: The separation of metals of the platinum group by hydrogen under pressure. M. KABATSHNIK and M. KATZNELSON: Amination of alkaloids with sodium and potassium amides. A. KLEBANSKIJ and K. CHEVYCHALOVA: Synthesis of β-chlorpropionic acid by condensation of phosgene with ethylene. P. BORODIN and M. GADD: An investigation of the radioactivity of the springs of the Ilmen district and of Lake Turgoyak (South Urals). M. CLAIRE: Some notes on the hydrogeology of the springs of the Ilmen district and of Lake Turgoyak (South Urals). V. LEVSHIN and M. ALENCEV: Researches on the phosphorescence of calcites. J. SALKIND, S. SONIS and N. BLOCHIN: Studies in the synthesis of vitamin A. (1) The action of magnesium-bromvinyl-acetylene on the β-ionone. (2) Biological properties of the product of synthesis. Z. KATZNELSON: The sources of development of the latero-ventral part of the body muscles and of the tail muscles in Amphibia. V. DONTCHENKO and N. MEDVEDEV: A case of dependence of success of interspecific hybridisation upon a single gene. DONTCHO KOSTOFF: Changes in karyotypes induced by centrifugation. V. CIVINSKIJ: The effect of fruiting upon transpiration. N. KALABUKHOV: The physiological peculiarities of the mountain and the plains sub-species of the forest mice (*Apodemus sylvaticus ciscaucasicus* Ogn. and *A. sylvaticus mosquensis* Ogn.).

MELBOURNE

Royal Society of Victoria, April 11. AUSTIN B. EDWARDS: Three olivine basalt-trachyte associations and some theories of petrogenesis. Investigation of the olivine basalt-trachyte associations in three Tertiary igneous provinces, in Victoria, at Otago in New Zealand, and at Kerguelen Island, supports the theory advanced by W. Q. Kennedy that alkaline lavas are the normal product of differentiation of an olivine-basalt magma, so long as there is no undue amount of contamination by contemporary syntexis. Desilication of basaltic magma by its assimilation of calcareous sediments has not occurred in either of the three provinces. In the absence of an immediately previous orogeny, such alkaline rocks will develop in a continental region as readily as in an oceanic region; but an orogeny appears to provide conditions favourable to large-scale assimilation of siliceous and argillaceous sediments, with an accompanying production of andesitic types.

Forthcoming Events

[*Meetings marked with an asterisk are open to the public.*]

Sunday, July 14

BRITISH MUSEUM (NATURAL HISTORY), at 3 and 4.30.—M. Burton: General Tour of the Museum.*

INTERNATIONAL CONGRESS FOR SCIENTIFIC MANAGEMENT, July 15–19.—Sixth Congress to be held in the Central Hall, Westminster, S.W.1.

July 15 at 12. Opening of the Congress by H.R.H. the Prince of Wales.

Chemistry and Citizenship

CHEMISTS, like members of other professional classes, remind themselves from time to time that their vision should extend beyond their professional interests and services into the wider field of the community at large, so that they may bring their specialised knowledge to bear on the problems which their own actions have raised. Not that scientific people are insensible to their duties as intelligent citizens—far from it; but they tend rather to measure their own success or failure in adding to the general store of knowledge, or power, or well-being through spectacles which leave out of focus important considerations none the less real because they are awkward. The physician strives to save life and prolong it; if he succeeds, we applaud him as indeed we should, for has he not contributed to human happiness? But is it, or is it not, the business of the medical man also to see that the effect of an increase in the expectation of life on, say, the vigour of the governing class, or the chance of employment, or the support of the aged, or the use of leisure, is properly examined? And if he takes up the study himself, since it is clearly impossible for him to refuse medical aid to the sufferer, is he in any better position than his patient to help in the development of a scheme of education and social order suited to the new conditions which he has created?

To judge by one or two lectures which have recently been delivered, chemists are giving attention to the social effects of their own chemistry and industry. Having invented means of producing goods with less labour (although part of the displaced labour has been absorbed in new directions of their own devising), some at least are wondering whether it is not after all their duty to do something rather more definite and vigorous about the social consequences. They are wondering whether the same amount of scientific study given to such disturbances of social equilibrium as is given to the material results of scientific inquiry might not have beneficial results in indicating the best directions of scientific development, as well as in alleviating the troubles which for all our science we have been unable to avoid. Thus Mr. W. M. Ames, in a lecture on "The Chemist and the Community" reported a little time ago in *Chemistry and Industry*, advocates the scientifically planned State as the logical sequel of the application of science to industry. He wants to establish it without interfering with the freedom of leisure, and without forgetting (as he claims rationalised industry has almost forgotten) that human nature has its failings. He proposes, for one thing, a reduction of working hours, and deplores that such a proposition has been allowed to become a political question instead of being treated as a problem of industrial management. He finds it hard to say whether or not science and human nature would come to blows during the evolution of the scientific State—for various reasons the information to be gleaned from the Russian experiment is not very helpful to others—but he declares that two million unemployed is a price we cannot afford to pay for the pleasure of muddling along.

Whatever we may think of the means available for its solution, there can be no argument about the problem. Each and every new scientific or industrial advance, whether it brings a new source of employment, a desired or enforced leisure, a longer lease of life, or a quicker way of killing people, sets up ripples and echoes which it is our

business to trace before they get beyond control and threaten to involve our social fabric in revolution instead of ordered evolution. We cannot stop learning, even to please superior people who have persuaded themselves that too much natural knowledge is antagonistic to their rules for human behaviour. They naturally prefer the latter (which admit of manipulation and alteration) to the former (which does not), and hence they complain that all this knowledge is doing us little good.

Our thesis is that more information about the social relationships of science would help to restore our balance and would lead to better government as well as better science. What, for example, is the proper attitude for scientific workers to take in relation to war? The chemist's part in modern warfare is popularly realised if not understood; and it makes good journalistic copy when normal manufacturing processes become the production of secret explosives, and poison gas exudes from every peaceful cauldron. Preparation for war does, however, call for the services of chemists, and Mr. R. Brightman, who a little time ago discussed at Manchester the place of professional organisations in society, asks scientific workers to formulate a definite ethical code towards preparation for war. In a recent issue of *The Chemical Practitioner* he points out that so long as there is real risk of war, the fullest resources of science should be used to make warfare efficient, economical and unlikely, but that "while it might be accepted as part of the scientists' general code that research work in connexion with general war needs was always legitimate, it might equally be held that research on agencies prohibited by international agreement or participation in large scale production of armaments in peace time was illegitimate".

The trouble is that any such scheme, to be effective, would have to be universal; unilateral action might well be a disservice to the cause of peace. What is the chemist to reply if he is asked to help in arranging protection for the civil population against aerial gas attacks? Is he to point to the Geneva Protocol and hope for the best, or is he to allow his natural humanity to overcome his faith in human nature? This very subject of the education of the public in means for dealing with gas attacks was quite lately discussed before the British Science Guild by Mr. J. Davidson Pratt, the general manager of the Association of British Chemical Manufacturers. The question of the scientific worker's duty in relation to the preservation of peace and to the provision of military necessities is obviously presenting doubts and difficulties to conscientious minds, which is all the more reason why the whole matter should receive earnest attention by professional organisations of scientific workers.

Mr. Ames truly says that if at any time the nation is drawn into a war the chemist's duty is the same as that of any other citizen; but that duty should not prevent him using his special powers and opportunities to strive with all his might against the warlike frame of mind and to harness the spirit of adventure to combat evils and distresses which familiarity almost persuades us to ignore. He finds the nobler adventure in a determined effort to provide work for everybody, and in doing so much he is doing more to undermine the causes of unrest.

Mr. Brightman thinks that scientific workers have come more and more to realise that, even in its narrowest sense, scientific or professional work is not something entirely apart from the life of society; that it cannot be truly isolated, and that it has to be integrated into the general life of the community. One of the ways in which this could be done more effectively would—as we have suggested before—be through the medium of the Press and of broadcasting. The social reformer gets ample opportunity for advocating his ideas for promoting the public advantage; his schemes for abolishing this and nationalising that. But the chemist (if we may take him as an example) speaks mostly through his own journals to his own people. It is necessary to impress on the public mind a picture of science in the making and science in application, to illustrate the aims, ideals and methods so familiar to the scientific worker but so little understood by the commercial public, to discuss the ways in which this new knowledge is being used, or might be used for the public good, and to examine with equal candour the possible repercussions which we would rather avoid. It is of no use trying to plan an unwilling State; nor will the State be willing until it understands a great deal more of the minds and the methods to be utilised. But it is learning by precept and by trial-and-error where organisation may usefully operate to the public profit, and where it still seems best not to limit individual freedom. The more it knows—not about chemistry, for example, but about the part which chemists play in national life—the

more will it be ready to listen to their advice; and the more chemists study the community, the more fit will they be to tender it.

Research workers cannot be a class apart in this modern world; they must mount the platform and advertise their wares. Individuals who have the ability as well as the knowledge can seek to use the popular Press as their tribune—and the Press will be willing enough if they attract readers; a science news service such as has been operating in the United States of America for some years past might be set up by a combination of professional organisations in Great Britain; and the universities might organise a comprehensive service in co-operation with the broadcasting authorities.

In any event, we shall not make the mistake of crying science as a panacea for all ills, for there are few of us who do not set great store by the preservation of moral and spiritual values; but we feel that in our scientific work we are carrying a responsibility which we cannot adequately discharge without public assistance in the widest and least mercenary sense of the term.

The Foundations of Modern Science

A History of Science, Technology and Philosophy in the 16th and 17th Centuries

By Prof. A. Wolf, with the co-operation of Prof. Dr. F. Dannemann and A. Armitage. (History of Science Library.) Pp. xxvii+693+68 plates. (London: George Allen and Unwin, Ltd., 1935.) 25*s*. net.

THE book before us deals not only with pure science, but also with technology and philosophy. It is thus able to place science in a frame of other knowledge, and show the relations and cross-connexions between them. This method is desirable, indeed necessary, if a true appreciation of the picture is to be obtained. The early development of modern science was inevitably influenced by the philosophic environment in which it grew, and gained much by the gradual improvements in scientific implements, and by the problems thrust upon science by medicine and technology.

It will be seen how wide is the field which Prof. Wolf sets out to cover. It comprises several subjects not usually included in histories of, or treatises on, science—an extension which certainly adds to the interest of the whole. But this volume is but part of the scheme. In the preface we read:

"The present book is complete in itself. It is, however, intended to be only an instalment of a complete history of science. The author proposes to deal with the eighteenth and nineteenth centuries next, and then with ancient and mediæval times. But each volume will be as nearly as possible self-contained."

This extract serves to place Prof. Wolf's work between the encyclopædic "History of Science" of Dr. G. Sarton and the various specialised histories of particular branches of science on one hand, and single volume histories of science on the other.

The two centuries under review open with scholasticism still a power, though a waning power, in the intellectual world. Scholasticism reached its zenith in the thirteenth century, when the acute mind of St. Thomas Aquinas put together a logical, and within its limits, a complete scheme of existing knowledge, based on the Christian faith as interpreted by the Roman Church, and Nature as described by Aristotle. Accepting these two authorities, the scholastic philosophy seemed to the late Middle Ages to follow by deduction both logically and inevitably. This is what Whitehead means when he describes modern science, which is primarily inductive and not deductive, as "a recoil from the inflexible rationality of mediæval thought". Wolf criticises this pronouncement, saying that "due regard for the stubborn facts of observation is an essential part of any thoroughgoing rationality". Here, I think, he somewhat misunderstands Whitehead's meaning. But he is right in pointing out the influence of the Pythagorean emphasis on number in forming the thought of Copernicus and Kepler, though he seems to miss the point that this "earlier Greek tradition" persisted through the Middle Ages, first as the leading philosophy, and then as a survival, underlying, as an alternative, the prevailing late medieval Aristotelianism.

Although Aquinas himself was ready to consider the possibility of a moving earth, the geocentric theory, in the minds of lesser men, had become part of scholasticism. Thus the Copernican revolution was not only a simplification, and therefore a mathematical improvement, on the cycles and epicycles of Hipparchus and Ptolemy, but also a threat to reduce the earth, the home of man,

from its central throne to the humbler rôle of one of the planets. Luther and his reformers opposed it from the beginning, and Catholic theologians only allowed it as a mathematical speculation. Hence, when Galileo confirmed it as physical reality by astronomical observations, and, greatly daring, set out for Rome to convert the Papal Court to Copernicanism, both scholastic philosophers and orthodox cardinals would have none of it.

Galileo's work in founding dynamics, if less spectacular than his discoveries in astronomy, was perhaps of even greater importance. Prof. Wolf gives a good account of this work taken in isolation. But here, as elsewhere in the book, there seems a certain want of appreciation of the connexions and cross-connexions which bind together the work of several men. As Mach pointed out, the fundamental dynamical investigations of Galileo, Huygens and Newton really mean the discovery of only one principle. It was an accident of history which caused force and momentum to seem simpler and more primary than Huygens' ideas, equivalent to our modern concepts of work and energy.

The chapter on scientific academies shows the great help given by them, through the association of men of science, to the early development of natural knowledge, and the account of scientific instruments makes clear the dependence of accurate measurement on the skill of the technician.

The story of the construction of the great Newtonian synthesis, in the more recent light which has been thrown on the points at issue, is well set forth in Chap. vii. The revolution in science begun by Galileo was thus, in all essentials, completed. Not until the present age was so complete a change in outlook produced in one lifetime and recognised as such by the instructed world. The full repercussion of Newton's work on philosophy was not felt until the eighteenth century, and is therefore outside the scope of the present volume, but the scientific effects were overwhelming and immediate.

The development of mathematics went hand in hand with the development of astronomy, and, if other branches of physics began each in isolation, they were preparing for mutual inter-action at a later date. Light was examined by Kepler, who gave a geometrical explanation of the telescope; Snell, who hit on the true law of refraction; Fermat with his principle of minimum time of passage which connected Snell's law with the velocities; Grimaldi, who first suggested seriously the wave theory of light; Huygens, with the principle that each small element of a wave front acts as the centre of an elementary wavelet; and Newton, who first gave the true theory of the colours of the spectrum.

Until the seventeenth century, little or no clear distinction was made between heat, fire and flame, and throughout that century there was controversy whether heat was essentially "fire atoms" or molecular motion—indeed Robert Boyle, who in general upheld the view that heat was "the super-induced commotion of small parts" of bodies, explained the gain in weight of a metal on calcination by the absorption "of atoms of fire". For a consensus of opinion about the nature of heat, men had to wait for Joule in the nineteenth century.

The vibrations of sounding strings were studied by Galileo, who realised that the period of vibration is the determining factor in the pitch of a musical note. The velocity of sound was measured by Gassendi and others, while Guericke, after inventing the air pump, showed that sound would not travel through an exhausted space.

The modern experimental science of magnetism and electricity was founded by Gilbert of Colchester. Descartes attempted to explain magnetism by an application of his general theory of vortices, but, except for various observations on the mariner's compass, not much more was done during the period.

Meteorology, like other sciences, depends on suitable instruments, and until the invention of the thermometer, barometer and rain gauge, nothing much could be done. But with them a number of continuous meteorological records were made in the seventeenth century. Among the navigators, William Dampier made observations on winds and ocean currents, while the physicists Halley and Hooke speculated as to causes.

At the beginning of the period, chemistry was subject to three main tendencies: (1) the alchemists' search for the philosophers' stone; (2) the use of chemical remedies in medicine, especially by Paracelsus; (3) the need of chemical knowledge in the mining industry. This last subject is of great interest; it is not often mentioned, and Prof. Wolf does right to bring it forward. As regards chemical theory, until Robert Boyle published the "Sceptical Chymist" in 1661, it was a mass of confused notions, in which explanations were sought in Aristotelian terms of occult qualities or 'substantial forms'. Boyle was followed by Lower and Mayow, who combined chemical with physiological researches, and did much to elucidate the process of respiration.

After chapters on geology and geography, we come to the biological sciences, which, subordinate to medicine at the beginning of the period, won an independent place in its course. A quite new

field of research was opened up by the invention of the microscope, while physiology was revolutionised by Harvey's discovery of the circulation of the blood. Thus Prof. Wolf passes to medicine, with an account of the most famous physicians of the time.

The chapters on technology show that, during the period under review, "science learned from existing technical methods rather than taught them". The converse effect only became generally important at a later date. But the accounts of agriculture, textiles, building problems, mining and mechanical engineering illustrate the gradual application of more systematic methods in industry. These accounts are accompanied by copies of many contemporary prints.

The chapter on psychology perhaps suffers somewhat by being placed before and not after that on philosophy. The chapter on the social sciences contains interesting reproductions of early Bills of Mortality and other examples of the introduction of statistical methods into the study of social phenomena, while it is shown that the problem in practical economics which occupied the statesmen of the time was based on the idea of increasing national wealth by a "favourable balance of trade", whereby not only necessary commodities but also an excess of precious metals might come from abroad.

The final chapter traces the formal separation of science from theology and then from philosophy, and their mutual reactions when each was pursued by methods of its own. In this chapter more might have been made of the fundamental change wrought by Galileo. His work replaced the homocentric philosophy of scholasticism, with space and time as unimportant categories, by a return to the concepts of Democritus, who visualised reality in terms of atoms and a void, and reduced the qualities of colour, sound, taste, hotness and coldness to mere sensations in the observer's mind. The rest of the chapter traces well the thought of such men as Bacon, Hobbes, Descartes, Spinoza, Locke and Leibnitz, and ends, as a book on seventeenth century science should, with Newton. Prof. Wolf is to be congratulated on a volume, which, if not perfect, is yet a notable achievement. W. C. D. DAMPIER.

The Salamander

The Anatomy of the Salamander

By Dr. Eric T. B. Francis. With an Historical Introduction by Prof. F. J. Cole. Pp. xxxi+381+26 plates. (Oxford: Clarendon Press; London: Oxford University Press, 1934.) 25*s*. net.

SALAMANDER is a name not unknown to folk-lore, mythology or even slang. Henceforward it must be more than a nominal acquaintance of every zoologist, without distinction of creed or class, for Dr. Francis has given us a book with a much wider appeal than its title would suggest. In his preface the author says that: "Its intention is to provide a general account of the anatomy and morphology of a tailed Amphibian—the Salamander, which shall, within limits, be comparable with the work of Ecker and Gaupp on its ecaudate relative—the Frog". There can be no doubt of his successful achievement of this object, and the two works are not only comparable but also complementary; the easiest way of discovering the latest morphological nomenclature and the most recent views on the homologies of anuran structures is to compare the relevant sections in the two books.

The system of the two is essentially similar. Each group of organs is considered separately, its components being described fully but concisely, and illustrated by numerous clear, diagrammatic figures; following each chapter are the pertinent references. But although the system is similar, there is one very important difference in the descriptive methods. Dr. Francis is never didactic, and in any instance where there are differences of opinion an impartial summary of the conflicting points of view is given. Though the book is primarily intended for the amphibian morphologist, whether student or teacher, it is these critical summaries, and the references, which render the volume so useful to other vertebrate zoologists.

The bibliography contains no less than 840 titles (of which only four per cent have not been personally examined by the author) and, though this testifies to the enormous amount of work which has previously been done on the subject, Dr. Francis is no mere literary compiler. There are numerous original observations, and the author has personally investigated all the structures he describes. Modern technical methods have been utilised to check the findings of earlier workers, and special or new methods are described where they have been found particularly suitable.

No work of this magnitude can be perfect in

every way. The arrangement of nearly all the figures on a series of plates at the end of the volume does not make for ease of reference, especially as many of them are exceedingly intricate; to follow the text in one place, the figure in another and find the meaning of an abbreviation on the plate (there are more than nine pages of these abbreviations) is no light task.

Again, the taxonomic and zoogeographical chapters are disappointing, for nothing is said of the numerous described subspecies of the salamander and only three 'varieties' are recognised. What the author's concept of a 'variety' may be is not explained, but as the '*var. molleri*' is said to occur all over the Iberian Peninsula side by side with the '*Forma typica*' it is presumably not the same as a subspecies. No explanation of the use of the name *molleri* (the date of which is wrongly given as 1896 instead of 1889) in preference to the older *galliaca* is offered, and the map showing the species as occurring in the Balearic Islands, Sicily, Crete and Cyprus is very misleading. But, since these chapters are merely incidental to the main theme, and are, moreover, merely repetitions of mistakes by other workers, they do not seriously detract from the value of the book for its primary purpose. There are also some slips (such, for example, as in references 779–781, where the author's name should read "Werner" instead of "Weliky"), which will prove troublesome to the student, and though trivial in themselves are blemishes on an otherwise admirable piece of work.

Modern Views on Magnetism

Magnetism and Matter

By Dr. Edmund C. Stoner. Pp. xv+575. (London: Methuen and Co., Ltd., 1934.) 21*s*. net.

DR. STONER and all physicists interested in magnetism are to be congratulated on the appearance of this admirable monograph. In 1926, the author published a book on the same subject, "Magnetism and Atomic Structure". The present treatise, far from being merely a revised edition of its predecessor, is practically an entirely new work, in which full justice is done to the considerable progress resulting from experimental and theoretical research in the course of the last ten years (electronic spin, quantum mechanics, etc.).

After a historical introduction, which makes delightful reading, short accounts are given of the necessary theoretical tools of classical and quantum physics in Chapters ii and v respectively, Chapter iii giving a lucid exposition of experimental methods and Chapter iv describing earlier results and theories (Ewing, Curie, Langevin, Weiss). After three chapters on the Zeeman effect (in atomic spectral lines only), magnetic deviation of atomic rays and gyromagnetic effect, an extensive review is given of diamagnetism (Chapter ix, pp. 251–279), paramagnetism (Chapter x, pp. 280–349) and ferromagnetism (Chapter xi, pp. 350–437), the author's interest being everywhere harmoniously divided between the exposition of facts and of their theoretical interpretation. Then follows an account of Kapitza's measurements in very strong fields (Chapter xii), of molecular magnetism (Chapter xiii) and of the magnetic properties of metals and alloys (Chapter xiv). The work ends with useful appendixes and an extensive author- and subject-index.

With a vast subject such as magnetism, it is often a very difficult question to what extent experiments and theories claim a general scientific interest. The author's choice in this respect is very much to be admired indeed; his own important contributions to the theory, for example, have been presented in the same objective manner as those of others, and he has shown a very wise self-restraint in practically leaving out such subjects as magneto-optics and magneto-electricity. At the same time, the reader gets a vivid impression that magnetism is a very living branch of physics nowadays; many of the theories recorded still bear a strongly speculative character, but the way in which it is done adds highly to the charm of the book. Consequently objections which here and there can be raised may easily be due to personal taste.

The classical discussion of the energy of a magnetised body in Chapter ii is, in the reviewer's opinion, scarcely a satisfactory basis for the general laws which are derived from it. More attention might perhaps have been directed to the calculations of Penney and Schlapp, which give an important contribution towards the understanding of the wide applicability of Weiss's law in paramagnetics. As regards anisotropy of ferromagnetic single crystals, it is questionable if the current atomistic explanation of this phenomenon can withstand the touch of criticism. Remarks like these, however, if valid at all, do not affect the intrinsic merits of Dr. Stoner's excellent book.

H. A. K.

Veterinary Helminthology and Entomology: the Diseases of Domesticated Animals caused by Helminth and Arthropod Parasites. By Prof. H. O. Mönnig. Pp. xvi+402. (London: Baillière, Tindall and Cox, 1934.) 30*s*.

PROF. MÖNNIG, who is professor of parasitology in the Veterinary Faculty of the University of Pretoria, is well-qualified to write a work of this character. The aim of his book is to give an account of the helminth and arthropod parasites of domestic animals and, at the same time, to stress those practical aspects of the subject most useful to the veterinarian. The morphology of the parasites concerned is dealt with in a general way and sufficient account is given about their general characteristics to enable specific parasites to be identified. The parasitic diseases themselves and their treatment come in for rather fuller consideration. The chief parasites of the common domestic animals of the world, and also kindred creatures affecting fur-bearing mammals, are included. If important parasites have been omitted it is only because, the author states, discrimination on this subject is difficult on the basis of existing knowledge.

The book is divided into four parts or sections, of which Sections I and II are brief (they occupy together less than 22 pages) and are mainly introductory. Section I is concerned with the general subject of parasitism, resistance and immunity, pathogenicity and kindred topics. In Section II methods of preserving and mounting material are described, but the part is devoted more especially to clinical methods of diagnosing parasitic diseases. The longest part of the book is Section III, on helminth parasites (more than 230 pages), while Section IV, on arthropod parasites, occupies about 133 pages. The author evidently favours the helminths more than the arthropods, and their treatment is often more detailed, apart from the fact that they include the larger number of species of veterinary importance.

The subject matter of the book is well arranged and thoroughly up to date, while the illustrations are admirably clear and well executed and the majority of the figures are new and original. The book will undoubtedly well serve the purpose intended, and should meet the requirements of both the student and practising veterinarian. It should also be on the shelves of zoological libraries.

Qualitative Analyse mit hilfe von Tüpfelreaktionen: theoretische Grundlagen, praktische Ausführung und Anwendung. Von Dr. Fritz Feigl. Zweite, verbesserte und vermehrte Auflage. Pp. xii+513. (Leipzig: Akademische Verlagsgesellschaft m.b.H., 1935.) 28 gold marks.

IT is gratifying to note that the second edition of this invaluable guide to 'spot' tests has been published within four years of the first edition (reviewed in NATURE of December 12, 1931), and that it has not been necessary to raise its price, in spite of the fact that it has been enlarged and partly rewritten. Actually, the number of pages has been increased by more than thirty per cent, much of the increase being necessary to include work, published and unpublished, carried out in the author's own laboratory.

Besides covering in the most detailed manner every variety of spot test for inorganic and for organic substances, the book contains 116 pages of theoretical discussion, under which head are considered complex-formation, co-ordination of elements, poly-acids, catalysed and induced reactions, the various groups 'specific' to particular metals and so on. Many of the tests appear twice in the book, according to whether *A* is used as specific for *B*, or *B* as specific for *A*. At the end of the book is found a tabular summary covering ten pages, an author index covering nine, and a subject index covering nearly nineteen. The utility of the book should secure for it a wide public, quite apart from its inevitable appearance on the book-shelves of every micro-chemist. A. L. B.

War Office. Textbook of Mechanical Engineering Pp. xv+690+xx. (London: H.M. Stationery Office, 1934.) 12*s*. net.

THIS is the best twelve shillings' worth of information on mechanical engineering we have ever come across, and it is scarcely possible to conceive a better guide for the young engineer. In it theory and practice are combined in an admirable manner, and it is full of those 'wrinkles' which only the experienced engineer can impart. It covers workshop practice, all the ordinary types of reciprocating steam, petrol and oil engines, boilers, power transmission, lubrication, air compressors and refrigeration. There are diagrams, tables, charts, bibliographies and a good index, and the information is conveyed with an economy of language which sometimes reminds one of the drill shed. The production of the book it may be presumed is the result of team work, but it is quite evident that a good deal of credit is due to the editor, whoever he may be. E. C. S.

A Guide to the Constellations
By Prof. Samuel G. Barton and Prof. Wm. H. Barton, Jr. (McGraw-Hill Astronomical Series.) (Whittlesey House Publication.) Second edition. Pp. x+74. (New York and London: McGraw-Hill Book Co., Inc., 1935.) 15*s*. net.

THE first edition of this atlas was noticed in NATURE of November 10, 1928 (p. 723). In the new edition the authors have made slight alterations to the text, necessitated by recent developments such as the discovery of Pluto. The charts themselves appear to be unaltered, and the opportunity has not been taken of introducing the new constellation boundaries as defined by the International Astronomical Union. This, however, is of minor importance to the class of readers for whom the book is intended, and who will find it not only an excellent help in becoming familiar with the constellations but also a trustworthy source of elementary astronomical information.

The Medical Curriculum in Great Britain*

University and other Qualifications

Training and Examinations

ENGLAND has been hearing a great deal about the training of medical practitioners. All through the spring months ran the long drawn examination by a Committee of the House of Lords of the evidence for and against the bill proposing that osteopaths should be accepted as medical men. The bill was withdrawn, and it may be hoped that the lay public accepted that decision with satisfaction, though it is doubtful whether they could follow the arguments of the medical experts who sought to emphasise the essential value of what was given by the orthodox medical curriculum in training the practitioners whom the country requires for its manifold services in matters of public and private health.

Now, immediately after the ending of this debate, comes a report of high authority confessing that the medical curriculum itself is in need of amendment, and proposing substantial changes. The fault here is of a very different nature and the contrast should be noted. The osteopath sought to be accepted as a medical practitioner on a scanty curriculum bent around a fundamental hypothesis of the cause of all diseases which had no relationship to the steady advances of scientific knowledge in biology.

Orthodox medicine moves forward in close harmony with every advance in modern science, gaining understanding of disease and power to control it from the physicist, the chemist, the zoologist, indeed from all except the successors of the old astrologist. Each such step forward in medical knowledge may mean the chance of its application to some individual patient, and the teacher of medicine, thinking of those patients whom his students may have to tend, feels his duty to be that no detail of possible value shall be omitted. So the student's memory is overburdened and he loses thoughtful education. The medical curriculum is not too scanty but too full.

The need for a revision of this curriculum—a rationalisation to use the latest phrase from the world of industry—has been urged again and again, by students as well as by teachers. There seems to be a greater difficulty in planning a course that shall combine education of a university type with adequate vocational training in the subject of medicine than is met with in engineering, chemistry or law. The medical man, when qualified by the final examination, is expected to be able in his independent judgment and knowledge to handle rightly one and all of the practical problems that may arise in human illness. There is no later stage of apprenticeship for him, and the routine training must be thorough and exact.

The general scheme of this training in its minimal form is outlined by the General Medical Council, a body which does not itself examine candidates or grant diplomas. Each university is free to arrange its own course of instruction and its examinations for its own degrees, provided that the standard for the latter does not fall short of the minimum prescribed by the General Medical Council. Outside London, this freedom has been used from time to time in remodelling the courses of medical education, and quite easily because each university could assemble its teachers and decide upon an agreed policy. But London in its hugeness was confronted with peculiar difficulties. The University of London contained not one but twelve medical schools, all teaching for the University degree but with teachers who until recent years did not feel inclination to obey a central University authority. Side by side with the University in the metropolis was another examining, but not teaching, body with power to grant a qualifying diploma, that of the Royal College of Physicians and Royal College of Surgeons. This Conjoint Board diploma was governed by its own curriculum, arranged in complete independence of the University of London and with its examinations graded in such a way that almost all the University of London students found it advantageous to take the Conjoint Diploma first, despite the additional and heavy fees entailed; and then a large proportion of them never troubled to complete their University course. With this alternative road to a vocational qualification lying open to its students, the University lost full liberty to make its own decisions as to the training of these men.

An added complication came from the medical schools of Oxford and Cambridge. These Universities

* Report of the Conference of Representatives nominated by the Universities of Oxford, Cambridge and London, the Royal College of Physicians of London, the Royal College of Surgeons of England, and the Society of Apothecaries of London, on the Medical Curriculum. Pp. ii+34. (London: University of London, 1935.)

granted a medical degree, but taught only the pre-clinical subjects. Almost all their students went for clinical training to London, to be taught in the curriculum of the University of London. Cambridge was eager for changes in the course of training, but its hands were tied because it had no power to change the routine of teaching in the London schools. Moreover, any alteration in its final examinations which might introduce difficulties for Cambridge students was open to the danger that they would simply cease to present themselves for the Cambridge degree. For the Cambridge and Oxford men, like those of the University of London, almost all secured their position in practice as early as possible by taking the separate Conjoint diploma of the Royal Colleges.

While Oxford and Cambridge were thus hindered in their desires for reform of the curriculum, London also lost some of its freedom for independent action owing to the presence of the students whom it welcomed from the older Universities. These men were not registered as students of the University of London, but Oxford and Cambridge would have felt the discourtesy if London had introduced large changes in its curriculum without inquiring how such changes would affect the course of clinical studies ordained, though not taught, by the two Universities for their students whom they sent to London. The only body that was really free for independent action was the Conjoint Board. It arranged a good practical curriculum and a sound clinical examination, though on the simple lines of a vocational training. Its demands could be less than those of a university, and it was in the position of established strength. Two thirds of the London students were content with the diploma of the Royal Colleges and never completed the University course.

These obstacles to independent action have been surmounted in the only possible way. In 1932 the Senate of the University of London invited the Universities of Oxford and Cambridge, the Royal College of Physicians of London and the Royal College of Surgeons of England to appoint representatives for a conference on the defects of the medical curriculum. The proposal was received with good will and friendliness by all. An executive committee was appointed, and in two years the Report of the Conference was issued, on April 30, 1935. Though so many bodies and so many different subjects in medical education were represented, the work of the Conference and of the Committee went forward so quietly that little discussion of the questions was excited outside the Conference itself, and the Report is signed with agreement of all its members. It is an excellent document, and the acceptance of its main recommendations and especially of its spirit by the university and other authorities concerned would improve notably the education of medical students in the metropolis. The number of the latter is larger than is commonly realised. The Medical Register shows a total of about 1,500 men and women accepted each year as newly qualified doctors. Approximately one half of this total for the whole of Great Britain receives clinical training in London. The Report has a larger responsibility than even the names of Oxford, Cambridge and London might suggest, for it considers the education of half the medical men in Great Britain.

The Report emphasises one leading principle, that education of intelligence is required, so that the student's mind may "acquire that kind of culture which survives the forgetting of facts". Again and again attention is directed to the excessive loading of the memory with details for the purpose of passing some examination which stands as a high fence before the student can pass from one closed field of the curriculum to another. Many of these facts resemble the leaden weights which a horse must carry for a handicap race, useless and discarded as soon as that particular race has been run. The Report aims at lessening the isolation of one field of knowledge from another in the progressive curriculum, seeking for example to carry physiology onward to help in experience at the bedside, while bringing illustrative material from the hospitals into the preclinical years to emphasise the aim of physiological or anatomical studies. The hope is to produce the trained intelligence, and the memory which is exact in that which must be remembered for the sudden needs of action or decision in medical work, but is not burdened with those innumerable details of secondary importance which any intelligent person would know how to find in a book when he needs them. That type of mind will not be produced unless the work of the curriculum allows reserve energy and time for thought. A lightening of the load as well as a modernisation of its content is required, and it is essential that the recommendations of the Report be judged with close attention to this primary need.

The Report does not suggest any change in the total period of medical studies for qualification, namely five years, or in its present division of two years for the preclinical period (anatomy, physiology, etc.) and three years for clinical studies. But the intermediate subjects of the preclinical years are to undergo some change. Anatomy and physiology, with biochemistry, will both receive rather less of the student's time, and they are to be illustrated towards the end of the period by

examples of derangement of normal structure or function as seen in hospital practice. In both subjects it is directed that the examinations shall not involve "burdensome memorisation of detail", structural or otherwise, but shall rather test the student's grasp of principles. Professors of anatomy and physiology are not likely to be dissatisfied with this. Their own courses of academic training for higher degrees in these subjects have generally been distinguished from that provided for medical students by the emphasis laid in examination on the comprehension and intelligence of the candidate rather than on a routine load of information. It is the type of medical examination hitherto in vogue which has insisted on minute topography or memorised physiology. But in one respect the physiologists until recently have been to blame, since they were slow to meet the needs of medical students by illustrating their science through observations on man or even on the mammal. It was once said that physiology never taught the essential facts of the catamenial period because menstruation did not occur in the frog. That reproach now belongs to past history.

Pharmacology is also eased, by attaching the subject to physiology, abolishing its special examination, and no longer requiring at this preclinical stage the purely artificial knowledge of doses of drugs and their therapeutic applications. But the leisure time that may perhaps be gained by changes in these three original subjects of the intermediate course is not left idle. Two new subjects are to be introduced, each on a minor scale. The first is an admirable choice, psychology or, as it might better be termed at this stage of the curriculum, the physiology of the mind and emotions. Eight lectures, presumably without practical experiments, are to be given and not to be followed by an examination. Medical psychology and psychiatry form a subject of immense importance both in the therapy of patients, whether physically ill or mentally afflicted, and in public health. But the subject has grown up in its own house apart from the so-called exact sciences. The medical student does not make acquaintance with it until near the end of his clinical training, and then too often in only a perfunctory way that makes him fail to grasp its high importance. In his clinical period he soon discovers that much of what is taught to him on any question in the wards lacks rigid scientific proofs, and he becomes habituated to a different set of values in the art of medicine. Psychology exists to him only in that later environment. The subject cannot but gain in strength if it is shown to be capable of a scientific exposition that will endure comparison with that of physiology, and its obvious interest may then prove powerful enough to determine some of the best of the younger men to devote their lives to the advancement of the science of mental diseases, a recruitment that is sorely needed.

The second new subject to be introduced is one which definitely links the preclinical with the clinical subjects, namely pathology in its general aspects including bacteriology. This is to be studied in the last two terms of the preclinical course, and with such seriousness that an examination in it is to be grouped with those on anatomy and physiology at the end of the preclinical course. This introduction is also a reasonable and good choice, for it prepares the student to think scientifically of disease by comparison with normal anatomy and physiology; but with the examination added it most emphatically cannot be regarded as a lightening of the curriculum at this stage. The general conceptions of pathology do not follow directly from the knowledge of normal anatomy and physiology. They are new phenomena which require time for their comprehension and some practical experience, whether this be got by laboratory experiments or by seeing human disease. Yet the student is expected to pass an examination in this new subject after a short course and at a time when he needs all his spare energy for ensuring success in the examination in anatomy and physiology which must be passed before he is allowed to move on to his clinical studies. Surely it would be wiser to give the preliminary course but to defer the examination until knowledge can ripen with fuller experience and with time for thought on that experience.

The advocates of pathology are continually increasing their claims on the medical curriculum. In 1922 the clinical period was extended from two years to its present time of three years, and that at once gave an extra year to pathology, which is taught or studied throughout all phases of the clinical period. Now, though normal anatomy and physiology are being pruned to a limited spread of growth in their short preclinical season, pathology and bacteriology are to be extended backwards for another six months, to take root in the preclinical time, to spread over all the three clinical years, and stand strongly as a separate subject in the final examination itself. One is reminded of the triumphant song of Psalm lx. "Moab is my washpot: over Edom will I cast out my shoe." But this conquest is no lightening of the burden of the curriculum, either at the beginning or the end. Academic pathology, as a science, may be more essential for the study of medicine than either anatomy or physiology, but it is difficult to justify two examinations in it when one suffices for each of the latter subjects.

The final examination in pathology, as at

present held, involves as burdensome a loading of the memory as the examinations indicated for amendment in anatomy and physiology; and it comes at a more grievous time when the student requires all the spare crannies in his memory for necessary details of clinical work. It would have been a real liberation for him if pathology had been satisfied with one examination only, about the end of his second clinical year, so that, well trained in rigid scientific thought by anatomy, physiology and pathology successively, he could then devote himself to his final clinical subjects and, under the guidance of clinical teachers who would also be his examiners, prove his intelligence in the application to medical problems of these fundamental scientific subjects. A modern clinician in a good hospital, whether he be surgeon or physician, is guided in all his thoughts by applied physiology and pathology: indeed he is more alert to employ physiological knowledge for the investigation of clinical problems than is the pathologist, who tends to restrict his outlook to morbid anatomy and immunology. It is essentially the clinician's duty to apply in his work the principles derived from the sciences of physiology and pathology, and to explain their application to the student when the latter has learned these sciences in their academic aspect apart from the individual patient. If the clinical teachers cannot use this knowledge in his work, the student will be driven to think that it is all artificial and a weariness added to his mind. It is not reasonable to impose at the end of the clinical period a separate examination controlled by pathologists who are likely to demand from the student, just when he is maturing to clinical skill, a greater load of pathological information than he or even a senior clinician can employ in work with patients.

For the clinical work of the final three years the Report has no considerable changes in view. It stresses that more attention should be given to attaining practical familiarity with minor ailments and with common diseases of the skin, eye and ear, which tend to be segregated in special departments of a hospital. The required time may be found in curtailing that of attendance on such major operations as in later practice will fall only to the surgical specialist. Emphasis is rightly laid on the need for fuller practical instruction in the psychological aspects of ill health; and a special course of lectures is demanded for public health and State medicine, including forensic medicine. All these are additions obviously needed for the education of the ordinary practitioner, but nothing has been put aside to make room for them.

The most fundamental change of all in the clinical period is that recommended for the sequence of the final examinations. Hitherto obstetrics and gynæcology have been grouped as a small subject, easily methodised in teaching, and often cleared away by the student as a preliminary to his more serious approach to medicine and surgery. That meant a lower standard of skill in a subject where recent developments in public health services have actually been tending to require that the practitioner shall at once be competent to assume the position of a consultant with ripe experience. So the order of examinations has been reversed, and obstetrics together with diseases of children and State medicine are to form a senior subject in Part II of the final, which cannot be passed until the student has completed his examination of medicine and surgery. This change would undoubtedly fit the doctor better for his important duties in relation to national health, though actually it cannot but constitute an increase in his curriculum, because a higher standard of knowledge will be demanded for subjects that at present are treated too lightly. The Report offers no advice as to the time when these different examinations may be attempted in the final period, but it is assumed that all can be completed by the end of the three years.

The formal decisions now lie with the Universities and the Conjoint Board. If the recommendations of the Report are generally accepted, the education of the doctor will be more intelligent and far better adapted to the needs of modern practice. But the examiners will still be waiting at the Caudine Forks. Unless they alter their present attitude and in advance of the examinations reassure the student that the change is real, he will continue to load himself as before with every odd scrap of knowledge that he fancies may be called for at his trial. Then the new subjects will be found to have added to the present burden of the curriculum and all will be heavier still. Someone recently compared the weight of kit carried by the British infantry soldier in comparison with his body weight and muscle to that which is the regulation maximum for horse and camel in the same scale of comparison. The infantryman would be fairly loaded at 30 lb., but his determination enabled him to struggle along with twice that weight as modern science altered warfare and new devices were continually added to his original kit. The medical student is in a like plight, and he too carries on. The difficulties of his toil have been recounted by the Dean of St. Mary's Hospital, Dr. C. M. Wilson, in an article justly entitled "The Student in Irons"*. If the examiners accept the spirit of the present Report, they can do much in helping to unshackle a very willing worker. T. R. E.

* *British Medical Journal*, March 12, 1932.

Biological Control of Coconut Scale in Fiji*

SUCCESSFUL INTRODUCTION OF A COCCINELLID BEETLE

By Dr. A. D. Imms, F.R.S.

MR. T. H. C. TAYLOR has recently prepared a lengthy paper describing biological methods of controlling the scale insect *Aspidiotus destructor* in Fiji. From the economic point of view, this pest causes extensive damage in Fiji to coconuts, bananas, 'yagona' and avocado. The present paper deals more especially with the insect in relation to the copra industry, of which it is a most serious enemy.

It is not known how, or exactly when, the scale insect became introduced into Fiji; but it was already a pest in the year 1912. Neither chemical nor mechanical methods of control for insects attacking coconuts can be satisfactorily employed in the islands on account of labour being expensive and relatively scarce. Furthermore, the coconut estates are not sufficiently localised to allow of a power sprayer being used without incurring excessive costs for transportation. Attempts were made to control the *Aspidiotus* in 1920, when certain parasites were introduced from Tahiti, notably the species *Aphelinus chrysomphali* and *Aspidiotiphagus citrinus*. In 1927, other parasites and also certain predators were imported from Java, but neither of these schemes of parasite introduction proved productive of appreciable economic results.

It was not until 1928, when several species of predators were obtained from Trinidad and introduced into Fiji, that a solution of the problem was obtained. The fact that certain Coccinellid beetles had been observed to be important factors in the repression of the *Aspidiotus* in Trinidad led to five species of the family being introduced into Fiji. The metamorphosis and biology of these insects are carefully described and figured. Of these, *Cryptognatha nodiceps* proved far superior as a controlling agent to any of the other four species, and attention was mainly centred upon it.

As a means of controlling the *Aspidiotus*, *C. nodiceps* proved to be a remarkable and spectacular success. Only nine months after the shipment was landed in Fiji, and liberations made, the scale insect was brought under control in all the more important islands of the group. After a further nine months, the scale was not only controlled on every single island, but also became so rare in many localities where it formerly abounded that living batches could only be found after much searching. Up to the time of writing his paper (July, 1934), Mr. Taylor states that the Coccinellid has not only reduced the appearance of the scale to negligible proportions, but is also apparently maintaining a permanent effective check upon it.

The complete success of the introduction of *C. nodiceps* is attributable to a combination of facts. First, it breeds continuously with a high rate of multiplication throughout the year in Fiji. It is a voracious predator, both as larva and adult, and in the latter phase it is long lived. Secondly, it has remarkable powers of dispersal. Thirdly, it has no serious natural enemies in Fiji. Finally, the *Cryptognatha* is able to survive even when the *Aspidiotus* has become reduced to a condition of great scarcity. In this connexion, the fact that it has an alternative host in another scale insect, namely, *Diaspis pentagona*, which is not a serious pest in Fiji, is important.

When a parasite or predator is introduced into a new country, where the *Aspidiotus* is rampant and occurring in outbreak form, it must be capable of multiplying and dispersing sufficiently rapidly to 'overtake' the pest in the worst outbreak. Also, having repressed the scale to an economically negligible condition, it must be capable of maintaining such a phase. It appears that none of the parasites previously introduced is capable of fulfilling these conditions and was consequently foredoomed to failure. Each individual parasite can only destroy one individual pest and none is capable of greater multiplication than the latter. It is only an insect like *C. nodiceps*, of quite exceptional voracity and with a very high multiplication rate, which can possibly control the outbreaks in question. Each individual *nodiceps* is capable of destroying hundreds of scale insects, in all stages, during its life and of bringing about a far greater destruction rate than that achieved by any of the parasites. Whereas the latter, theoretically at least, are capable of maintaining the scale in a non-outbreak condition, their biological attributes are such that they are inherently incapable of bringing about that condition in the first place.

* "The Campaign against *Aspidiotus destructor*, Sign. in Fiji." By T. H. C. Taylor (with three sections by R. W. Paine). *Bulletin of Entomological Research*, 26, 1-102, with 40 text-figures; 1935.

Obituary

Dr. Herbert H. Thomas, F.R.S.

THE sudden death on May 12 of Dr. Herbert H. Thomas, petrographer to H.M. Geological Survey, at the early age of fifty-nine years, has caused a sad gap in the ranks of British geologists, and deprived a large circle of a warm friend and helpful adviser. To brilliant academic attainments he added further lustre during his subsequent geological career. His wide interests and accurate knowledge were readily placed at the service of those who consulted him, and his sympathetic nature made him an unusually large circle of friends. To know Thomas was to love him.

Educated at Exeter School, where his family then lived, Thomas entered Sidney Sussex College. In due time he obtained a first class in Part I and in Part II of the Natural Sciences Tripos; was awarded the Harkness Scholarship (1898) and the Sedgwick Prize (1906). In 1898–1901 he acted as assistant to Prof. W. J. Sollas at Oxford. In 1901 he was appointed geologist on H.M. Geological Survey and was assigned to the South Wales district; just at the time when the classic district of Llandeilo was about to be entered by the surveyors.

Thomas, trained at Cambridge, had the good fortune to be associated with T. C. Cantrill, who was a pupil of Lapworth at Birmingham. Both these officers had been imbued with the work of Lapworth and of Marr and others of the Cambridge School on the Lower Palæozoic rocks. At the same time, Sir Jethro Teall had been appointed director of the Survey. The conditions were therefore exceptionally favourable to the adoption by the Geological Survey of Lapworth's threefold classification of those rocks which is now in universal use in place of Murchison's classification, previously used on its maps and in its memoirs. Thomas remained on the field staff until the completion of South Wales in 1911, when he was appointed petrographer—a post for which his training and interests in mineralogy eminently fitted him. He retained, however, a keen interest in the older rocks of South Wales, and frequently returned to attack their problems. Several papers appeared in the *Quarterly Journal of the Geological Society* jointly with O. T. Jones and with A. H. Cox.

In later years, Thomas's official duties brought him into intimate contact with the officers of the Scottish branch of the Geological Survey who were engaged in examining the Tertiary igneous rocks of the west of Scotland. When he was president of Section C of the British Association in 1927, he gave a brilliant address on the Tertiary volcanic history of north-west Britain. His interest in mineralogy, which had begun in his youth among the mine-heaps of Cornwall and Devon, was maintained throughout his career, as instanced by his valuable contributions on the minerals of the Trias of the south-west of England and papers on minerals and optical apparatus which were contributed to the Mineralogical Society, of which he was an active member.

Largely through association with T. C. Cantrill, Thomas took a keen interest in prehistory, and his wide knowledge of igneous rocks and their distribution was readily placed at the disposal of many visitors to the Geological Survey offices in Jermyn Street, who brought for investigation, stones, axes and other objects of archæological interest. By his fortunate acquaintance in the field with the igneous rocks of Pembrokeshire, he was able conclusively to solve the mystery of the blue-stones of Stonehenge, which had previously been assigned to many and diverse sources, and to show that they had been derived from a small area surrounding Carn Meini in the Precelly range.

Thomas was awarded the Murchison Medal in 1925 by the Geological Society of London, of which he was secretary from 1912 until 1922 and vice-president from 1922 until 1924. He also served on the Council of the Mineralogical Society. He was elected to the Royal Society in 1927, and at the time of his death was on the Council. He is survived by his widow, one son and one daughter.

Mr. J. E. Quibell

THE death is announced of James Esward Quibell, well known as an Egyptologist, at the age of sixty-eight years. Born at Newport, Shropshire, he was educated at the Newport Grammar School and at Christchurch, Oxford, of which he was an exhibitioner. After taking honours in Classical Moderations and the Final School of Natural Science, he engaged for a time in teaching; but travel in Egypt attracted him to archæology. He joined Prof. Flinders Petrie, assisting in the excavation of Coptos, Nagada, El Kab, Hierakonpolis and other sites. After a brief period of study at Berlin, he was appointed to the Catalogue Commission of the Egyptian Museum, Cairo, and in 1899 became an inspector in the Egyptian Antiquities Department.

Quibell conducted excavations in Upper Egypt and at Saqqara for a number of years and then in 1913 was made keeper of the Egyptian Museum, a post which he held until his retirement in 1925, although for the last two years of his tenure he acted as Secretary-General to M. Lacau, Director-General of Antiquities. Two years later he suffered serious loss in the death of his wife, a daughter of Principal Pirie of the University of Aberdeen, herself a distinguished archæologist. Notwithstanding the break in his life occasioned by this loss, he continued to pursue his archæological studies in Egypt almost to the end. He leaves behind him a record of sound and methodical work which has not always been so widely or so fully recognised as it deserves.

News and Views

Dr. Bernard Smith and the Geological Survey

DR. BERNARD SMITH, who has been appointed to succeed Sir John Flett as director of the Geological Survey of Great Britain, joined the Survey as a geologist in 1906, became district geologist of the Cumberland Division in 1920, and was appointed assistant to the director in 1931. In 1902 he had entered Sidney Sussex College, Cambridge, where his uncle, Charles Smith, author of many well-known books on mathematical subjects, was master. Taking a first class in both parts of the Natural Sciences Tripos and gaining the Harkness Scholarship for geology in 1906, he maintained his College's fine record for producing first class geologists. The Harkness Scholarship has been won by Sidney men six times since 1893. Bernard Smith's work on the Geological Survey and his researches pursued during vacations earned him a Geological Society award in 1913 and the Bigsby Medal of that Society in 1927. He was elected a fellow of the Royal Society in 1933. He is the author of many papers on stratigraphy and on the glaciology of Cumberland and North Wales, of many contributions to the memoirs of the Geological Survey, and of a well-known textbook of physical geography. His work on the Survey, particularly on the coal and iron-ore deposits of Cumberland, has brought him into contact with practical problems in which the Geological Survey and its Museum are so closely concerned. We may congratulate him on being selected to direct the progress of the Geological Survey in the first year of the second centenary of its work, and it may augur well that the new director, chosen at this historic moment in the life of the Survey, bears the name of the "father of English Geology", William Smith.

Prof. A. P. Karpinsky and the U.S.S.R. Academy

AMONG the delegates present at the recent celebration of the centenary of the Geological Survey of Great Britain was the veteran geologist, Prof. A. P. Karpinsky, president of the U.S.S.R. Academy of Sciences, Leningrad. Prof. Karpinsky is well known to British geologists, and was elected a foreign correspondent of the Geological Society of London so long ago as 1898. He became a foreign member of the Society in 1901 and received the Wollaston Medal in 1916. He is now in his ninetieth year, and has been a member of the Academy of Sciences in Leningrad for nearly fifty years, and its president for twenty years. The honorary members of this Academy include Sir F. G. Hopkins, Lord Rutherford, Sir Charles Sherrington and Sir Robert Hadfield. At a small luncheon given by Sir Robert Hadfield on July 10 in honour of Prof. Karpinsky, at which there were present, among others, Sir F. G. Hopkins, president of the Royal Society, Prof. W. W. Watts, president of the British Association, and Sir John Flett, director of the Geological Survey, Sir Robert recalled that Faraday was an honorary member of the Academy. He added: "As a metallurgist, I can speak with the highest approval of the splendid work of the two famous Russian scientists of the past, Demetri Tchernoff, who I believe was a member of the Academy, and Sergius Kern. From the research work of both these metallurgists I greatly benefited in my younger days." After the luncheon, the guests had an opportunity of seeing some interesting exhibits brought together by Sir Robert Hadfield, including a model in modern rustless steel of the famous iron pillar at Delhi, Mr. F. J. Halnon's bronze group symbolising "A Legend of Metallurgy", and objects illustrating results of investigations of specimens of steel made by Faraday at the Royal Institution between the years 1819 and 1824 and described in Sir Robert's book "Faraday and his Metallurgical Researches".

South African Protectorates and British Pledges

MINISTERS of the Crown have shown a somewhat tardy but earnest desire to allay public uneasiness lest further steps should be taken to carry out the undertaking of the British Government to hand over the three South African native protectorates to the tutelage of the Union Government without any opportunity being given for the expression of the views of the native population on the proposed transfer. The ground for this fear has now been removed by an official reaffirmation of the pledges given when the South Africa Bill passed through Parliament. In the *aide-memoire*, which was handed to the Prime Minister of the Union of South Africa by the Secretary of State for Dominion Affairs on May 15 last, now published as a White Paper (Cmd. 4948), explicit reference is made to the undertakings that the inhabitants, both native and European, of the Protectorates would be consulted, and Parliament given an opportunity to express its views, as precedent conditions which must be observed before transfer takes place. This memorandum goes on to state that the Government has expressed its view to General Herzog that not only is the time not ripe for such consultation of the inhabitants, but also that the information at its disposal indicates that native opinion in the territories is very strongly opposed to the transfer. This statement will bring reassurance to those who have felt apprehension at the way in which the situation has appeared to be developing in the last twelve months, and also it will give them no little gratification by its firm, but at the same time conciliatory, attitude in asking for the co-operation of the Union Government with the administration of the territories during the next few years in a policy which will convince the native population that the Union Government is working with the local administration in a real and generous desire to develop and improve conditions in the territories.

Committee Against Malnutrition

THE Committee against Malnutrition has issued for publication a memorandum which has been sent to the Advisory Committee on Nutrition of the Ministry of Health. The Committee considers that the full application of modern advances in the knowledge of nutrition would effect a general raising of the standard of health comparable to that which followed the lessening of disease by the construction of an adequate system of public sanitation. It is necessary not only to provide food of good quality, in sufficient amounts, but also to ensure the correct relation between the component foodstuffs. This can only be done by allowing an appreciable margin over any minimum standard hitherto formulated: the Committee considers that there is evidence that many lowly paid and unemployed families cannot purchase enough food to allow such a margin. The purchase of foodstuffs of special value will be at the expense of the cheaper energy-producing foodstuffs; dietary studies have shown that the change over to vitamin-rich food takes place automatically with increasing income. The addition of vitamin concentrates to the diet is deprecated. The Committee recommends that the precise food values of commercial preparations should be published by the Advisory Committee on Nutrition of the Ministry of Health, and that processing and dyeing foodstuffs should be prohibited. The view is put forward that all school children should receive half a pint of milk a day and nursing and expectant mothers at least one pint, with a scale of charges on a fair income basis. The Committee also expresses the opinion that the notion of minimum diets should be condemned.

Vitamin Standards

AT the request of the Health Organisation of the League of Nations, the Board of Trustees of the United States Pharmacopœia has consented to make generally available the standard cod-liver oils, prepared for use in the United States as secondary standards for vitamins A and D. The distribution of these oils will not be made through the national distributing centres as in the case of the primary vitamin standards, but direct to individual users. They may be obtained from Mr. E. Fullerton Cook, Chairman of the Committee of Revision of the U.S. Pharmacopœia, 43rd Street and Woodland Avenue, Philadelphia, Pa., U.S.A. It should be clearly stated whether vitamin A oil or vitamin D oil is required. A charge of 2.50 dollars is made for containers holding 30 c.c. A sum to cover the cost of the quantity required should be sent by international money order with the application. The oils will be sent post paid to their destinations. These reference oils are checked each six months biologically against the international standards by at least six laboratories, and their potency should therefore be increasingly dependable. Secondary standards of vitamins A and D are of considerable importance to British users, as it has not been possible to supply the primary international standards of these vitamins in quantities sufficient to enable them to be used for routine assays.

The Hæmatopoietic Liver Substance

THE *Yorkshire Post* of July 9 directs attention to the recent isolation by Dr. H. D. Dakin, who is a former student of the Yorkshire College in Leeds, and West, of a substance effective in causing blood regeneration in pernicious anæmia; the paper describing the investigation is published in the *Journal of Biological Chemistry*, vol. 109, p. 489; 1935. The material is obtained from liver extract by precipitation with Reinecke acid; the precipitate is decomposed with the aid of dimethylaniline and the active principle afterwards purified by salting out with ammonium and magnesium sulphates and sodium chloride. It appears to be of protein nature: on hydrolysis, an aminohexose similar to glucosamine was isolated together with lysine, arginine, glycine, leucine, hydroxyproline and aspartic acid; cruder preparations also contain histidine, glutamic acid and possibly traces of phenylalanine. Pepsin hydrolyses it to a slight extent, erepsin completely though slowly. The compound produces a good reticulocyte response in cases of pernicious anæmia in doses of 80 mgm. when given by subcutaneous or intravenous injection. Dakin and West's paper indicates that a distinct advance has been made in the problem of isolating the liver principle active in pernicious anæmia.

Broadcasting and the Jubilee Naval Review

FEW events of outstanding national interest now take place unaccompanied by a broadcast commentary. The Silver Jubilee review of the Fleet by His Majesty the King provided yet another demonstration of the use and efficiency of the national broadcasting service by distributing an eye-witness account of the scene and action of the review at the actual time of the event. On this occasion, the series of broadcasts was given by two naval officers located at the foretop on board H.M.S. *Royal Sovereign*, one of the ships taking part in the review, and occupying a very advantageous position from the commentators' point of view. A short-wave portable radiotelephony transmitter installed in the *Royal Sovereign* was used for the purpose of communicating the commentary to a receiver suitably located at Southsea Castle on the mainland. The signals thus received were transmitted by land-line to Broadcasting House, whence they were distributed in the ordinary way through the National stations. The programmes broadcast included a description of the scene at Spithead on the night preceding the review, with the 160 or so ships of all classes correctly assembled in position. On the actual day of the review, July 16, separate commentaries were arranged to describe the scene when H.M. the King received the Royal Salute, and then proceeded to sail up and down the lines of battleships; and finally at night a description of the illuminations of the fleet and the firework displays was given from the vantage-point of the *Royal Sovereign*. Four microphones were employed to pick up the gun salutes, cheers of the ships' crews and other characteristic sounds. As is now usual on such occasions, suitable recordings were made of the programmes to enable these to be repeated later, particularly for the benefit of Empire listeners.

A New Subtractive Colour Film

THE Eastman Kodak Company has introduced a new 16 mm. cinematograph colour film. This is known as the Kodachrome film. It differs from many other colour films now available in that the colour effects are produced 'subtractively'. The superimposition of 'minus' colours is used to yield the final colour. For example, a blue is produced by placing a minus green (magenta) on a blue-green (minus red), green by minus blue (yellow) on a minus red and so on. This is, of course, the ordinary principle of three-colour printing, but to apply it to this process has involved the use of a film coated in three layers. Each of these layers records one of the primary colours only. The top layer is sensitive to blue and transmits only green and red; the second layer records green and transmits red, while the last layer of all records only red. The film is exposed in the ordinary way and has a sensitivity which is said to be about half that of the normal film used for black-and-white cinematography. Processing is divided into a number of separate processes: (1) Development to negative. (2) Bleaching and clearing to get rid of the developed silver. (3) Exposure and redevelopment to positive. This redevelopment is carried out with a 'dye-coupling developer' which attaches a blue-green dye to the silver produced by development. All three layers are treated indiscriminately up to this point. Then follow further stages. (4) Bleaching the two upper layers; silver chloride is formed in place of the silver in these layers and the blue-green dye in them is destroyed. (5) Exposure and redevelopment of the two upper layers with a magenta coupling developer. (6) Bleaching the top layer and destroying the magenta dye. (7) Exposure and development of the top layer with a yellow coupling developer. The pictures so formed are continuous in tone.

Spelæological Research in Great Britain

A PROPOSAL to form a central organisation for the co-ordination of research in the caves and pot-holes of Britain is to be discussed at an inaugural meeting to be held on July 27 at the Museum, The Wardwick, Derby. Among those taking an active part in forwarding the movement are Prof. L. S. Palmer (Hull), Mr. A. Leslie Armstrong (Sheffield), Dr. J. W. Jackson (Manchester), Dr. A. Raistrick (Durham), Mr. H. Brodrick (Birkdale), and Mr. C. R. Hewer (Bristol University Spelæological Society). Prof. L. S. Palmer will act as chairman of the meeting, when aims and methods which will best promote systematic exploration of British caves on comprehensive lines, embracing all relevant forms of evidence, will be discussed. The proposal most favoured at present is the constitution of a British Spelæological Association, which would lead the way to a standardisation of technique and afford opportunity for co-ordination of results. Cave exploration in Britain has by no means been neglected, as the exploration of Kent's Cavern, Torquay, and Boyd Dawkins' classic work on "Cave Hunting" bear witness. The pot-holes clubs and antiquarian societies of the north of England have devoted considerable attention to it, and the activities of the Bristol University Spelæological Society, Mr. Leslie Armstrong and Prof. Palmer have been remarkably fruitful in additions to archæological knowledge, especially of the palæolithic period. It is felt, however, that co-operation between individuals and organisations interested in the problems of cave-dwelling man and his environment will facilitate further research and preserve the enthusiasm of explorers from unprofitable, and even harmful, activity by ensuring greater uniformity in the observance of scientific methods of exploration—a view in which archæologists, at least, will heartily concur.

Lulham Memorial Fund

MISS ROSALIE LULHAM, who died on December 28, 1934, was well known as a field naturalist and for her work as a teacher of natural history. During the last year of her life she was actively concerned in planning a course of training in natural history for students, teachers and others with previous scientific training, who, to quote her own words, "wish to make that practical study of living things both outdoors and indoors, which would enable them to teach live Natural History, making it the absorbing and enlightening subject it may be". Such a course of training is being established at the Froebel Institute, where she worked for thirty-eight years, and where the tradition of her teaching is living and growing in the Natural History Department built up by her efforts. The College of the Institute at Roehampton Lane, London, S.W.15, with its spacious grounds and its proximity to Richmond Park, offers excellent scope for practical study in natural history, and it has been suggested that a Lulham Memorial Fund be opened with the object of equipping the Science Department for advanced study in natural history. We trust that this appeal will meet with ready response not only from those who, directly or indirectly, shared the inspiration of her teaching, but also from those who believe that there is a real educational need for encouraging the teaching of biology through the study of living Nature. Donations should be sent to Dr. A. B. Rendle, c/o British Museum (Natural History), Cromwell Road, London, S.W.

Television in the Cinema

CAPTAIN A. G. WEST, of the Baird Television Co., Ltd., gave a very instructive address to the Cinematograph Exhibitors' Association at Cardiff on June 26. A summary of this address appears in the *Electrician* for July 5. He pointed out that the only possible waves that can be used to produce high-definition pictures are ultra-short waves the lengths of which are not greater than 10 metres. If a 6-metre length is used, then the necessary breadth of the band need lie only between 5·9 metres and 6·1 metres. If it be operated on 300 metres, it would interfere with many of the broadcasting stations in Europe. Ultra-short waves have almost the same properties as waves of light and thus cast shadows. The transmitting aerials on the top of the Crystal Palace tower are

700 ft. above sea-level and in most directions give an effective range of transmission of about 40 miles. In his opinion, the best all-round wave-length for television is 7 metres, which does to a certain extent curve round hills to more distant points. A large number of tests have been carried out in all parts of London in receiving pictures from the Crystal Palace transmitter. Excellent pictures have also been received at some fifty sites ranging from Southend to Maidenhead and from Hatfield to Sevenoaks. In two years time, it may be possible to buy a complete set for the home for about 35 guineas. For cinema work, he thought that the best method is to use an intermediate film. A film is taken of the scene to be transmitted. It is then developed, fixed, washed and dried before being televised, the whole operation being less than two minutes. The first cinemas to receive their programmes by television would get them by radio transmission links. Later on, the big central radio transmitter might conveniently be replaced by a central distributing exchange point, which would receive the televising waves by cable from the outside point possibly twenty miles away.

Italian Breakwater Construction

On July 9, at the invitation of the Council, a special lecture, illustrated by lantern views, was delivered at the Institution of Civil Engineers, by Prof. E. Coen Cagli, of the School of Engineering of Rome. Prof. Cagli reviewed very exhaustively the progress made during recent years at Italian harbours and gave particulars of the present accommodation and equipment at the leading ports. He related how, on his recommendation, following an official visit a number of years ago to Great Britain for the purpose of studying British methods and practice, the vertical wall type of breakwater came to be adopted in Italy, and he stated that, with the exception of an unfortunate experience at Catania, attributable to absence of vertical bond in the structure, the results had been uniformly successful. He described the catastrophic storm of March 26–27, 1933, which caused the displacement of 700 lineal metres of newly constructed breakwater at that port and compared it with the similar catastrophe which befell the second arm of the Mustapha Jetty at Algiers on Feb. 2–3 of the following year (vide NATURE, **135**, 143, Jan. 26, 1935), giving it as his opinion that these two incidents, on an analysis of the attendant conditions, only served to confirm his judgment in favour of the vertical wall breakwater. This type, moreover, had received further support from a series of experimental tests with small scale models, which he had been conducting with the co-operation of Prof. Stuckey at the hydrological laboratory of the University of Lausanne. Prof. Coen Cagli closed his lecture with a statement of the series of conclusions at which he had arrived on the basis of his experimental investigations.

Foundation for Theoretical Biology at Leyden

To promote the study and work in the field of theoretical biology, a foundation for theoretical animal and human biology has been established at the University of Leyden. In memory of Van der Hoeven (1801–68), professor of zoology in the University and author of the "Philosophia Zoologica", it is called "Prof. Dr. Jan van der Hoeven Stichting voor theoretische biologie van dier en mensch". The chief objects of the foundation are: (1) to arrange for lectures at the University of Leyden; (2) to bring Leyden biologists who are interested in theoretical biology into contact with their colleagues in Holland and abroad; and to promote the co-operation of theoretical biologists all over the world, for example, by arranging international symposia on theoretical biology; (3) to publish articles on theoretical biology; (4) to found a library on this subject. The directors of the Foundation are: Dr. C. J. van der Klaauw, professor of general zoology at the University of Leyden, Dr. J. A. J. Barge, professor of medical anatomy at the University of Leyden, and Dr. Adolf Meyer, professor of theoretical biology at the University of Hamburg.

U.S. Stratosphere Balloon *Explorer II*

MISFORTUNE has attended this latest attempt at stratosphere research. An account of the careful preparations that had been made jointly by the National Geographic Society and the U.S. Army Air Corps appeared in NATURE of June 22 (p. 1026) and the largest balloon ever designed was scheduled to be ready by June 1. A message in *The Times* of July 12 reports, however, that whilst the gondola was being attached on the previous day, the balloon burst for some unaccountable reason; the 375,000 cu. ft. of helium were lost, and the five men working below had to jump for their lives to escape from the falling mass of the collapsing envelope. From the brief report it would appear as though the whole of the 8 tons upward force was too much for the initial cylindrical form assumed by the envelope, with the result that the top blew out.

The New York Aquarium

THE thirty-eighth annual report of the New York Zoological Society includes the report of the director of the Aquarium, Mr. Charles M. Breder, Jr., assistant director (June 1934). Some of the larger exhibits, including aquatic mammals, have been discontinued, but there is a larger number of fishes, so that the total number of species and specimens is greater than before. The work of the laboratory for the most part was concerned with studying various details of aquarium operation for the improvement of life conditions of fishes in captivity, including water chemistry, control of parasites and bacteria, food and breeding. A new antiseptic, 'mesthiolate', was found to be of distinct value in the control of secondary bacterial infection and in overcoming attacks of the protozoan *Costia*. Young brine shrimps, *Artemia salina*, reared from dried eggs supplied by the San Francisco Aquarium Society, have proved an excellent food for the sea-horses and other small fishes. With some little trouble, the shrimps may be raised to a considerable size suitable for larger species.

'Spot' Tests

THE British Drug Houses, Ltd., London, N.1, has recently published a fourth edition of its book of reagents for 'spot' tests and delicate analysis (2*s*. 6*d*., postage 4*d*.). The application of sixty-seven organic reagents is described, nearly twice the number given in the first edition which was issued three years ago. References are appended to each monograph. In addition to descriptive matter relating to 'spot' tests as applied to micro-analyses, the book includes adequate working details for many colorimetric determinations and larger scale methods of analysis in which organic reagents are employed. This firm also makes a 'spot' test outfit and issues a price list of the reagents mentioned in the book. The fact that the latter has reached a fourth edition in three years indicates that the use of these reagents is extending.

Congress of Phonetic Sciences

THE second International Congress of Phonetic Sciences will be held in London on July 22–26, when the following subjects among others will be discussed: the physiology of the voice, evolution of speech in the individual, its evolution in the history of mankind, influence of heredity, gesticulation, psychology of speech, the deaf-mute, problems of practical instruction in language, use of the gramophone, and speaking films. Further information can be obtained from Miss Parkinson, International Phonetic Congress, University College, W.C.1.

International Congress on Population Problems

AN International Congress for the Scientific Investigation of Population Problems will be held in Berlin on August 26–Sept. 1 next. Arrangements for the Congress are being made by the International Population Union in association with the German societies for the study of race, hygiene, statistics and public health. The president of the Congress is Dr. Eugen Fischer, director of the Kaiser Wilhelm Institute for Anthropology, Human Heredity and Eugenics, Berlin. The scientific proceedings of the Congress will be conducted in general and sectional meetings, the latter providing for communications dealing with population statistics, population biology and race hygiene, social, economic and psychological population problems, and medicine and hygiene. Specific topics of discussion are "The Problem of Births", "Town and Country", "Racial Hygiene", and "The Protection and Consecration of Life". The General Assembly of the International Union for the Scientific Investigation of Population Problems will be held on Monday, August 26, under the presidency of Sir Charles Close. The delegates will be received by the Government of the Reich, the city of Berlin, and the Oberbürgermeister of Potsdam. Visits will be paid to scientific institutions, labour corps camps, etc., and arrangements have been made for an excursion to Saxon Switzerland. Particulars of the arrangements for the Congress may be obtained from the central office, Einemstrasse 11, Berlin, W.62.

Beit Memorial Fellowships for Medical Research

AT the meeting of the trustees of the Beit Memorial Fellowships for Medical Research on July 12, it was announced that Prof. T. R. Elliott, professor of medicine in the University of London, and Prof. E. D. Adrian, Foulerton research professor of the Royal Society, have been appointed trustees in succession to the late Sir John Rose Bradford and to Sir Charles Sherrington respectively. Elections to fellowships were made as follows, the proposed subject and place of research being given in each case after the new fellow's name. *Senior Fellowship* (value £700 per annum): Mr. R. Hill, to continue his studies on the respiratory function of hæmoglobin (Physiological Laboratory and the Molteno Institute, University of Cambridge). *Fourth Year Fellowships* (value £500 per annum): Dr. R. Gaddie, to continue his research on the metabolism of heart muscle (Departments of Medical Chemistry and Materia Medica, University of Edinburgh); Dr. J. M. Robson, to continue his work on the hormonic factors concerned in the maintenance of pregnancy and initiation of parturition (Institute of Animal Genetics, University of Edinburgh, or the School of Agriculture, University of Cambridge); Dr. F. G. Young, to study the diabetogenic factors of the anterior pituitary gland (Department of Physiology and Biochemistry, University College, London). *Junior Fellowships* (normal value £400 per annum): Dr. A. R. Todd, molecular structure of vitamin B_1 (Department of Medical Chemistry, University of Edinburgh); Mr. R. J. Kellar, the problem of nephritis and high blood pressure associated with pregnancy (London laboratories of the Royal College of Surgeons, and the Obstetric Unit, University College Hospital, London); Mr. N. L. Edson, fat metabolism and ketogenesis (Institute of Biochemistry, University of Cambridge); Dr. M. H. Salaman, investigation of the antigenic structure of the vaccinia virus (Lister Institute of Preventive Medicine, London); Dr. J. D. Fulton, experimental chemotherapy of malaria (London School of Hygiene and Tropical Medicine); Dr. Adèle H. Rosenheim, chemical nature of antibodies, especially those in antityphoid sera (Lister Institute of Preventive Medicine, London). The honorary secretary of the Beit Memorial Trustees is Prof. T. R. Elliott, University College Hospital Medical School, University Street, London, W.C.1.

Leverhulme Research Fellowships and Grants

TWENTY nominations have been made to Leverhulme Research Fellowships tenable for varying periods up to two years. The new fellows and their subjects of research include the following: Dr. W. N. Bailey, senior lecturer in mathematics, University of Manchester, the study of functions of hypergeometric type; Prof. D. B. Blacklock, professor of tropical medicine, University of Liverpool, a study of the present practice of hygiene (including rural hygiene) in certain Eastern countries; Mrs. M. G. Blacklock, curator of the Museum, Liverpool School of Tropical Medicine, a comparative

study of the organisations for the improvement of health of women and children in Eastern countries; Prof. C. Daryll Forde, professor of geography and anthropology, University of Wales, Aberystwyth, field study of the economy of a West African village community; Mr. S. D. Garrett, formerly assistant plant pathologist, Waite Agricultural Research Institute, University of Adelaide, the biological antagonism of the soil microflora towards root disease fungi of crop plants; Mrs. M. M. Hasluck, the unwritten law of Albania; Mrs. K. Lonsdale, research worker, Royal Institution, relation between structure and physical properties of organic molecules; Mr. E. P. Mumford, late director, Pacific Entomological Survey, Honolulu, terrestrial and freshwater biota of the Marquesas Islands; Dr. R. G. W. Norrish, Emmanuel College, Cambridge, the mechanism of certain chemical reactions; Mr. F. R. Perry, Research Dept., Metropolitan-Vickers Electrical Co., Ltd., the study of overvoltages due to lightning on transmission lines; Mr. L. R. Wager, lecturer in mineralogy and petrology, University of Reading, the tertiary igneous history of East Greenland; Mr. W. D. Ware, washery supervisor, Cefn Coed Colliery, Crynant, South Wales, research on the lower part of the Coal Measures and Millstone Grit in Pembrokeshire.

SEVEN grants in aid of research have been made by the Leverhulme trustees. They include grants to the following: Dr. P. Ford, head of Department of Economics, University College, Southampton, for statistical inquiries into sources of family income; Mr. R. D'Oyley Good, head of Department of Botany, University College, Hull, for a botanical survey of Dorset; Prof. J. W. Heslop Harrison, professor of botany, Armstrong College, Newcastle, for genetical and evolutionary studies with special reference to closely allied species and local races; Mr. J. W. Layard, to study the social anthropology of north eastern Malekula and allied cultures; Prof. J. W. W. Stephens, emeritus professor of tropical medicine, University of Liverpool, for a treatise on blackwater fever in its historical, clinical and other aspects.

Announcements

THE fifth Congress of Biological Chemistry will be held at Brussels on October 23–25. Further information can be obtained from the general secretary, M. R. Fabre, 149 rue de Sèvres, Paris.

IN a recently published pamphlet entitled "The Wasp" by Dr. W. B. R. Laidlaw (Edinburgh: John Baxter and Sons, Ltd. 3*s*.), the subject of the specific differentiation of the males in the genus *Vespa* is specially dealt with. The diagnostic characters concerned are illustrated by coloured and other plates together with tabular keys. The distribution of the genus in Scotland has also been specially studied by the author.

BOOTS' PURE DRUG CO., LTD., Nottingham, have recently issued a booklet with a useful thumb index, describing briefly their special medical products, with their modes of issue and prices. It is stated in the preface that all products must satisfactorily pass analytical tests and where necessary are examined bacteriologically and pharmacologically. Many of these special products are submitted to clinical trial before issue. The booklet has been specially compiled for the information of the medical profession.

THE National Botanic Gardens of South Africa has issued a seed list of seeds available from the plants grown in the Gardens at Kirstenbosch, Newlands, on the flank of Table Mountain. In addition to the African species grown here, there are also seeds of a certain number of exotic species of economic value, but perhaps even more interesting to British botanists will be the list of seeds available from the plants in the Karoo Garden, Whitehill. Applications for packets of seed have to be made to the Director at Kirstenbosch.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

A chemist in the Admiralty Chemical Pool—Secretary of the Admiralty (C.E. Branch), London, S.W.1 (July 22).

A full-time graduate assistant master for electrical engineering and mathematics at the Paddington Technical Institute—Education Officer (T. 1), County Hall, London, S.E.1 (July 22).

A temporary lecturer in mathematics (woman) at Bingley Training College—The Education Officer, County Hall, Wakefield, Yorks (July 24).

A lecturer in physics at Saint Luke's College, Exeter—The Principal (July 27).

An assistant with experience of the building industry at the Building Research Station, Garston, near Watford, Herts—The Director (July 27).

An assistant director and a secretary-statistician to the director of an industrial survey of South Wales—D. J. Davies, 1 St. Andrew's Place, Cardiff (July 29).

An assistant lecturer in metallurgy (founding) in the University of Sheffield—The Registrar (July 31).

A lecturer in the Department of Mechanical Engineering, Robert Gordon's Technical College, Aberdeen—Secretary (July 31).

Six gazetted civilian workshop officers for the Indian Army Service Corps (Mechanical Transport)—Secretary, Military Department, India Office, S.W.1, marked Mechanical Transport Recruitment (July 31).

A chemist in the Fulham Power Station—Town Clerk, Dept. 6, Town Hall, Fulham, S.W.6 (August 6).

Regius professor of zoology in the University of Glasgow—Private Secretary, Scottish Office, Whitehall, London, S.W.1.

A lecturer in physics and mathematics in the Rotherham College of Technology and Art—Director of Education, Education Offices, Rotherham.

Assistants for field and drawing-office work, Air Ministry—Secretary (W.B. 9, Room 161), Air Ministry, Adastral House, Kingsway, London, W.C.2 (by postcard).

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 110.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Artificial Radioactivity of the Rare Earth Elements

WE have now completed a preliminary survey of the Fermi effect (radioactivity produced by bombardment with neutrons) with all the elements of the rare earth group except illinium (61) and thulium (69). The results are summarised in the table below.

Z	*Element*	*Isotopes*	*Half-life*	*Relative Intensity*	*Hydrogen Effect*	*Active Nucleus*
57	Lanthanum	139	1·9±0·2 days	0·5	12	La^{140}
58	Cerium	140, 142	no activity			
59	Praseodymium	141	19±0·5 hours	0·9	—	Pr^{142}
60	Neodymium	142, 143, 144, 145, 146	no activity			
62	Samarium	144, 147, 148, 149, 150, 152, 154	*c.* 40 min. and a much longer period	0·03	—	? ?
63	Europium	151, 153	9·2±0·1 hours	19	40	Eu^{152} or Eu^{154}
64	Gadolinium	155, 156, 157, 158, 160	no activity			
65	Terbium	159	3·9±0·1 hours	0·6	—	Tb^{160}
66	Dysprosium	161, 162, 163, 164	2·5±0·1 hours	>30	20	Dy^{165}
67	Holmium	165	2·6±0·2 hours	>30	15	Ho^{166}
68	Erbium	166, 167, 168, 170	*c.* 7 min.	0·03	—	?
			1·6±0·2 days	0·3	—	?
70	Ytterbium	171, 172, 173, 174, 176	*c.* 3·5 hours	0·03	—	Lu^{176}
71	Lutecium	175	4·0±0·1 hours	1·0	—	Lu^{176}

The source of neutrons consisted of up to 400 millicuries of radon in contact with powdered beryllium, and the irradiation of the specimens was carried out in most cases in a large block of paraffin wax. The oxides of the rare earth elements were irradiated and measured as films containing about 0·3 grams/cm.^{2} and a similar film of silver oxide was irradiated at the same time. The relative intensities quoted in the fifth column of the table give a rough estimate of the activity per gram atom of the element when irradiated to saturation in the wax block in terms of the activity of the 2·33 min. period of silver irradiated under the same conditions. An entry "no activity" in the table indicates that the activity was less than 0·01 that of silver.

The most remarkable feature of the results is the intense activity produced by neutron bombardment of europium, dysprosium and holmium. These elements should prove useful as detectors of neutrons. The high activity shown by some of the rare earths makes it necessary, however, to take special care to ensure that weak activities ascribed to other rare earths are not due to the presence of a small amount of a highly active element. We have, therefore, examined in most cases specimens which on spectroscopic examination showed only traces of impurities, or specimens prepared in two different laboratories. In addition to those prepared by one of us (J. K. M.) we have used specimens of lanthana, praseodymia, neodymia and dysprosia, purchased from Messrs. Adam Hilger, Ltd., which on spectroscopic test are found to be free from other rare earths and contain only traces of other elements. We are indebted to Prof. G. Urbain for specimens of holmia, erbia and lutecia with which we have obtained the same results as with our own preparations.

We have confirmed the 19 hour period of praseodymium and the 40 minute period of samarium discovered by Fermi[1] and his co-workers but we have been unable to find an activity with an intensity greater than 0·01 on the silver scale for neodymium or for gadolinium, for which Fermi reports periods of 1 hour and 8 hours respectively. We are also unable to confirm the 5 minute period reported by these workers for praseodymium. On the other hand, we have found a considerable activity for lanthanum with a period of 2 days whilst Fermi reports that this element is inactive.

In an earlier letter[2] one of us (S. S.) reported periods of 2·9 hours for erbium and 2·5 hours for ytterbium, but the specimens examined were of doubtful purity. These results we now find are probably due to contamination with small amounts of holmium, as the purer specimens now studied give the periods quoted in the table. The erbia used in the later experiments was derived from a long series of fractionations as bromates and gave the same results as that supplied by Prof. Urbain. We have now examined a specimen of ytterbia separated from lutecia and other earths by the electrolytic method as insoluble $YbSO_4$. It gives a very feeble activity which is indistinguishable in period from that of lutecium and is probably due to residual traces of that element. The residual earths after the separation of ytterbium consisted chiefly of lutecia and gave a strong activity identical in period with that found for Prof. Urbain's specimen of lutecia.

The similarity in the periods found for the strong activities of holmium and dysprosium is somewhat curious. After the first observations had been made, the bromate fractions from which the specimens had been taken were submitted to another 1,000 crystallations and the specimens finally studied gave absorption spectra which showed that they were free from dysprosium and holmium respectively. Furthermore, specimens of dysprosia from Messrs. Hilger and of holmia from Prof. Urbain gave the same results as our own preparations.

It seemed possible that both elements might give rise to the same active product, namely, $_{66}Dy^{165}$ by the following nuclear reactions:

$$_{66}Dy^{164} + {}_0n^1 \rightarrow {}_{66}Dy^{165} \quad . \quad . \quad . \quad (1)$$

$$_{67}Ho^{165} + {}_0n^1 \rightarrow {}_1H^1 + {}_{66}Dy^{165} \quad . \quad . \quad . \quad (2)$$

Nuclear processes of type (2) in which heavy particles are emitted usually show a hydrogen effect of unity. (Fermi, loc. cit.) We have, therefore, determined the hydrogen effect for both elements and find that it is large. Reaction (2) is therefore improbable and the

similarity in the periods of the products from holmium and dysprosium must be regarded as a coincidence.

We are indebted to Imperial Chemical Industries, Ltd., for a grant which has largely defrayed the cost of this investigation.

Artificial Radioactivity of Dysprosium and other Rare Earth Elements

IN their pioneer work on artificial radioactivity through neutron bombardment, Fermi and his collaborators announced the discovery of the activity of some of the rare earth elements, namely, of lanthanum, praseodymium, neodymium, samarium and gadolinium. Recently, Sugden[1] found that terbium shows an appreciable, and europium a very strong, radioactivity after bombardment with neutrons. We find that dysprosium shows an unusually strong activity due to $_{66}Dy^{165}$ under the action of slow neutrons; so far as we can ascertain, it is the strongest activity found hitherto. So little as 1/100 mgm. of dysprosium gives an easily detectable radioactivity after bombardment with neutrons from a source containing a few hundred millicuries of radium emanation.

As dysprosium is one of the most abundant yttrium earths, it will be present in detectable amounts in many preparations of such earths, and care must, therefore, be taken in interpreting the results of the activation of the elements of the yttrium group. One of the holmium preparations investigated was, however, found to be practically free from dysprosium, and decayed with a period of 35 hours. We find that erbium decays with a period of 12 hours, ytterbium was found to have a half-life value of 3·5 hours*, while lutecium decays much slower, having a period of about 5 days.

The periods and relative intensities of the rare earth elements 59–71 (praseodymium – lutecium) are seen from the following table, which also includes a comparison of the intensities obtained when the preparations were activated until the maximum activity under the action of neutrons slowed down through the presence of large blocks of paraffin wax. The table contains also the half-value thickness in aluminium of the β-rays emitted.

Element	Half-life	Relative Intensity	Half value thickness (in cm.)
59 Praseodymium	19 h[2]	4·5	0·045[2]
60 Neodymium	1 h[2]	0·04	
62 Samarium	40 m[2]	0·6	
63 Europium	9·2 h[1]	39	0·04
64 Gadolinium	8 h[2]	very low	
65 Terbium	3·9 h[1]	2·5	
66 Dysprosium	2·5 h	100	0·025
67 Holmium	35 h	20	0·04
68 Erbium	12 h	0·35	0·03
70 Ytterbium	3·5 h*	0·25	0·04
71 Lutecium	about 5 d	about 1	
47 Silver	2·3 m	8	0·03

* The weak activity observed is possibly partly due to the presence of traces of dysprosium; investigating a commercial preparation of ytterbia, Sugden (l.c.) found a period of 2·9 hours.

We find for the upper limit of the continuous β-spectrum of dysprosium an energy of $1{\cdot}4 \times 10^6$ e.v. and for that of holmium $1{\cdot}6 \times 10^6$ e.v. The activity of dysprosium obtained through the action of fast neutrons was only 1/100 of that measured in the presence of paraffin wax, Fermi's coefficient α being thus 100, while in the case of holmium we find $\alpha = 20$. The rare earth preparations investigated were given to us by the late Baron Auer von Welsbach.

Enzyme Catalysis of the Exchange of Deuterium with Water

IN a further study of this reaction[1], we have found that the (first order) velocity constant depends markedly on the pressure of the hydrogen, being in fact inversely proportional to the square root of the pressure.

Sets of simultaneous measurements were made (at 37°) using equal samples of the same washed bacterial suspension (Bact. Acidi Lactici) so that all conditions could be made identical except the pressure.

The results of two typical sets are shown in Fig. 1, where the logarithm of the final deuterium concentration in the gas (C) is plotted against $p^{-1/2}$, that of the initial concentration (C_0, common to the set) being plotted on the axis ($p^{-1/2} = 0$).

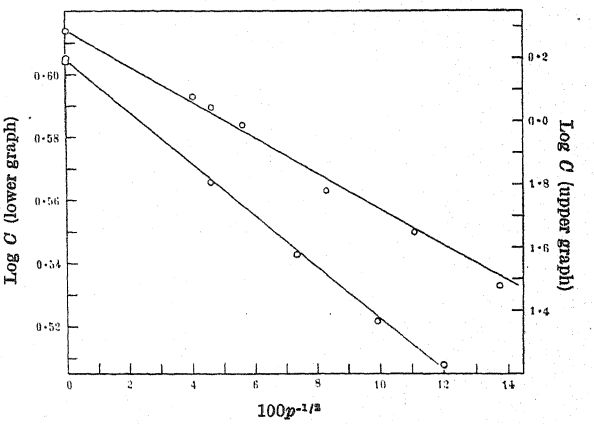

Fig. 1.

In these two sets, the number of bacteria present happened to be practically the same (8×10^{11}) but the times of reaction (t) were respectively 1212 min. (upper set) and 180 min. (lower set). The graphs, therefore, correspond to the equation

$$\log C_0 - \log C = Ktp^{-1/2} \qquad (1)$$

where K has the values 0·0047 and 0·00453 respectively.

It was found in all cases that, during the course of the reaction, the number of living bacteria, as

shown by the viable count, was diminishing rapidly (half-life period two to three hours), but this does not appear to affect the catalytic power. In fact, experiments made with the same suspensions after these had been kept for six days yielded practically the same value for the velocity constant.

A similar lack of correlation between enzyme activity and viability has been observed in the case of oxidative mechanisms[2].

From equation (1) we conclude that, as in the analogous case of metallic catalysts for which the same dependence on pressure has been established[3], the reaction takes place in two stages :

$$HD + 2B \rightleftharpoons HB + DB,$$
$$DB + H_2O \rightarrow HB + DHO,$$

(where B represents a catalytic 'centre') of which the second is much the slower and, therefore, the rate-determining stage.

We are attempting to estimate the rate of the first stage reaction also, by the use of parahydrogen and the $D_2+H_2 \rightarrow 2HD$ reaction.

Precision of Line Standards

DR. W. EWART WILLIAMS has recently published in NATURE[1] an interesting article on "Light-Waves as Units of Length". In a memorandum entitled "Les idées actuelles sur la définition de l'unité de longueur"[2], which appeared in 1927 (and which I admit is now somewhat out of date), I discussed this question in detail, and the conclusion at which I arrived was on the whole but little different from that of Dr. Williams. There is, however, one point which I should like to touch upon again in reply to the doubt expressed by him regarding the accuracy of 0·2 μ attainable with line standards.

The doubt stated by Dr. Williams is based principally on the evident impossibility of defining to a precision of ± 0·03 mm. the centre of a fiduciary line magnified 300 times, such as shown in the photograph illustrating his article, and he adds that the uncontrolled variations in the conditions of illumination necessarily involve greater errors than indicated above.

In considering the reading of a single fiduciary line, I would in the first place point out that the reproduction in NATURE by no means represents the appearance of a line as seen through the microscope of a comparator. The photograph was taken at a frontal distance of about one millimetre. The illumination was by means of a prism and therefore strongly tilted in the direction of the line, which exaggerates its defects. In the second place, it is not the centre of the line that is read, but its axis, viewed by symmetrical setting between the two threads of the micrometer situated on either side. The evaluation of the two boundaries of the line, in conformity with the definition recently laid down in detail for line standards, is much more precise than the reading of the centre. Finally, as to the effect of the lateral inclination of the light beams, the experiments of MM. Volet and Bonhoure[3], in which the source of light is moved systematically to the utmost extent first to the right and then to the left of the same line, have not occasioned apparent displacements greater than 0·6 μ. The possible uncertainty due to a faulty adjustment of the illumination cannot therefore exceed a very small part of this maximum. I would add that the line reproduced in the illustration is the worst line, given by way of example, of the worst of our old prototypes, bar 26, which has been in constant use for forty-six years. The addition several years ago of a more recent prototype to the working standards of the International Bureau has prepared the way for its withdrawal.

It must not be forgotten, however, that the reading of a line viewed separately has no significance whatever. Each bar has two similar lines, traced consecutively by the same tool on surfaces polished in the same way and cut in the same manner. Must not any systematic error in the viewing of lines be eliminated for a double reason? The two lines are seen under microscopes similar in all particulars; and the bar is intended to serve only in comparison with another bar read by the same observer under the same microscopes provided with the same illumination.

Moreover, the evaluation of a bar is not determined by one reading of the lines in a single position of the bar. A series of comparisons with another bar includes twelve observations, six on each bar in turn, each observation being the mean of two readings. Eight series are executed, including every symmetrical position of the bar with regard to the comparator and consequently to the illumination (which remains fixed) and to the observer. For all major comparisons, many other checks are taken advantage of by comparisons with other bars which are taken in groups of five or six, in all possible combinations two by two, so that finally the value attributed to a bar is the result of not less than five hundred readings of each of its lines. Those who are prepared to accept the result of the calculation of probabilities applied to metrology may deduce therefrom that it is sufficient to make each duplicate reading of a bar with a precision twenty times less, that is, about 4 μ for a double reading of the bar itself, or, if one makes use of a magnification of 300, then something less than a millimetre. Even by making use of the photograph reproduced in the article, similar reasoning (in which, however, I have little confidence) would lead to a higher degree of accuracy than 0·2 μ for the evaluation of a line standard.

It is always interesting to seek for explanations of facts and I have not failed to do so. But the true answer to the doubt expressed by Dr. Williams is the direct affirmation of experience. It is found in practice that a line-bar of good quality compared with a group of others reproduces the same value, whatever may be the experimental conditions and whoever may be the observer, with a precision of ± 0·2 μ. This evaluation of accuracy is that of the strictest metrologists, among whom I number myself. There are metrologists, not without distinction, who would accept a still more favourable evaluation[4].

It remains now to explain the discrepancy pointed out by Dr. Williams, of 0·0036 A. between the value of the cadmium red wave-length as determined by the Reichsanstalt and by the National Physical Laboratory. If as he thinks probable, this

difference arises from the initial comparison of the national prototypes with the Sèvres working standards, it would correspond to an error of 0·56 μ between the British and German prototypes. But this supposition has recently been shown to be unfounded. The prototype No. 16 of Great Britain and No. 18 of Germany have since been returned to Sèvres, and with the obliging collaboration of a metrologist from the N.P.L., have been very carefully compared one with the other. The result showed, within about 0·06 μ, the same difference that we attributed to them previously.

ALBERT PÉRARD.

Sèvres.
May 24.

[1] NATURE, 135, 459 and 496; 1935.
[2] "La Création du Bureau international des Poids et Mesures et son Œuvre". Paris: Gauthier-Villars, 1927, p. 259.
[3] "Procès-Verbaux des séances du Comité international des Poids et Mesures", Deux. série, 15, 30; 1933.
[4] See Ch.-Ed. Guillaume, "Les Récents Progrès du Système métrique", pp. 14 and 15; 1934.

M. PÉRARD'S justification of the metrologist's claim of being able to compare two line standards with an error not exceeding ± 0·2 μ is based entirely on the degree of concordance observed in practice when large numbers of readings are taken in all possible positions. Equally so, we find when we analyse the purely interferometric data for the number of waves contained in an optical gauge of a metre length, the concordance between the individual results is even more striking.

Michelson has expressed the opinion[1] that if the standard metre had been an optical gauge instead of a line standard, the accuracy of the wave-length determination could be increased five-fold. Sears and Barrell[2] estimate that the overall probable error associated with the optical measurement is ± 0·016 μ, while the average accuracy of repetition in the measurement of line standards is taken to be of the order of ± 0·25 μ.

Unless the difference between the values of Kösters and of Sears and Barrell can be ascribed to uncertainties regarding the lengths of the line standards, one is driven to the conclusion that the discrepancy is due to a lack of symmetry in the hyperfine structure of the red cadmium source. With such asymmetry, the value obtained for the wave-length is an oscillating function of the path difference in the interferometer. This effect is much more pronounced with the Michelson instrument, or the Twyman and Green modification of it as used by Kösters, than with the Fabry-Perot interferometer employed by Sears and Barrell. The higher the effective number of reflections, the more closely does the interference fringe correspond to the real intensity distribution of the spectral line itself. Sears and Barrell used plate separations of 1/12th and 1/9th metre as basic units and were not able to detect a measurable difference in the wave-length value.

Hence, in spite of M. Pérard's assurances, there still remains the possibility that the experimental error in line standard comparisons may in reality be two or three times larger than his estimate.

Origin of Tektites

GLASSY particles weighing between approximately a gram and occasionally a hundred grams have been found at several widely separated places on the earth's surface. The explanation of the origin of these natural glass particles, known as tektites, is complicated by the series of peculiar forms which they exhibit and the size of the areas over which they are found. They have been collected from each of the States in Australia, and because of this continental distribution are frequently called Australites. Several theories of their origin have been advanced and discussed in NATURE, vols. 131 and 132, 1933. Dr. L. J. Spencer and others suggest that the tektites are 'aerial fulgurites', the post-impact result of a great meteorite striking the earth in a region of sandstone or desert sand. Comparison is made with the silica-glass from the meteor craters at Henbury and Wabar. The main difficulty in accepting their theory is the wide distribution of the particles wherever they are found. The W. H. C. Shaw collection of Australites was made over a region of 30,000 square miles on a "monotonous limestone plain" on the southern shore of Australia[1]. Furthermore, Fenner points out that the region is "without any siliceous rocks whatever"; hence a fulguritic origin for these Australites appears to be impossible.

Another theory assumes that they were originally extra-terrestrial bodies and that at the time of a meteoritic passage through the earth's atmosphere they became liquid from the frictional heat (Michel, Suess, and others)*. As they cooled, the combination of air resistance and some rotational motion of their own caused them to take on the lens, tear-drop, or dumbbell shapes which are observed[2]. There are several theoretical difficulties with the possibility of such a shaping process, as well as the observational objections discussed below.

There are numerous bodies which are known to have descended through our atmosphere from interplanetary space. These objects comprise three classes of meteorites: stones, stony-irons and irons. The irons show a peculiar crystalline structure, known as the 'Widmanstätten figures', which disappears when heated above 850° C. The presence of these figures to within a few millimetres of the surface of the iron meteorites indicates that they were not heated to this temperature during their brief meteoric flight. The stones also show no internal indications of having been heated to this temperature. Further, the melting point of Darwin glass, a form of tektite, is about 1,400° C.[3]; it is composed very largely of silicon dioxide (about 87 per cent SiO_2) and its coefficient of thermal conductivity is about 0·002 cal. per cm. degree sec. (fused silica, glass and sandstone). The coefficient of thermal conductivity for iron is about 0·10 in the same units. Hence we see that a lower temperature is required to affect the iron meteorites than to melt the tektite, and that the rate of heat transfer is about fifty times greater for the iron meteorite than for the tektite; yet the iron meteorites give no evidence of having been heated to an internal temperature† of 850° C. It therefore

* The combustion theory of Lacroix appears artificial; the reaction suggested probably could not occur during a meteoric flight, as the meteoric phenomenon is now interpreted.

† A low internal temperature for iron meteorites in flight through the atmosphere is assumed as the result of the 'ablation' (liquification and immediate removal) of the heated surface. This process is generally believed to absorb most of the heat of the atmospheric resistance[4]; freshly fallen meteorites are seldom described as being more than "milk warm".

appears impossible that sufficient heat from atmospheric friction was transferred to the interior of the tektites to allow them to melt and take on the observed shapes.

For the reasons given above we consider that, as yet, no satisfactory meteoritic theory has been advanced to explain the origin of tektites.

Philosophy and Modern Science

I AM sorry if my psychological knowledge fails to reach the standard required by Dr. Dawes Hicks[1]. My book[2] has, as a matter of fact, been the subject of favourable notice in three psychological journals, though I cannot claim the universal agreement that would apparently be necessary to make it convincing to Dr. Dingle. I have done my best to explain what I mean by the terms used.

What Dr. Dawes Hicks calls a 'sensum' seems to be what Russell called a 'sense-datum'; and I do not use sense-data, partly because most of the alleged existing sense-data are not perceived and therefore are not part of our fundamental knowledge, and partly because some inference and refinement are necessary before we can pass from our immediate knowledge to even the perceived sense-data. I am not sure whether I accept Dr. Hicks's other definition; his words 'mental act' seem to presuppose that we know what we mean by mind and that there is some kind of activity in merely having a sensation; the former seems to me to be posterior, not anterior, to sensation, and the latter is I think untrue. When my eyes are open I am aware of various patches of different shapes and colours, which disappear when my eyes are closed. Those are what I mean by a sensation. They seem to be immediate and not the result of any activity on my part; they just happen. In the case of sensations of sound even the minor preliminary activity of opening my eyes is unnecessary.

Again, Dr. Hicks's definition of a concept presupposes the existence of universals, and apparently denies the existence of different degrees of universality. Here I definitely disagree. A single observation of Neptune is merely a bright spot surrounded by blackness, with appropriate modification in the case of a photographic observation. It is only when many observations are available that we can form the idea of a single body moving in a definite way; generalisation has already been applied in thinking of Neptune at all. The individuals are merely a certain finite number of bright spots.

I am quite clear that I do not experience another person's sensations. He can tell me about them, and I may believe what he says; but a long process of inference has been involved before I can attach a meaning to this statement and put them on a similar footing to my own. It is well known to astronomers that the observations of different observers need certain corrections before they become comparable among themselves.

I agree with Dr. Campbell's second paragraph; I should also agree with his first if I was sure that he does not regard my view as a philosophy. I regard it as a description of the method of acquirement of knowledge. For example, what I call a concept is substantially what Pearson called a construct; but I prefer not to use the latter term because it suggests acceptance of the phenomenalist philosophy, while I think that there is nothing in my work that could not be equally well accepted by a critical realist.

Though I do not necessarily agree with Prof. Levy entirely, I consider him clearly right in objecting to Prof. Dingle's adoption of universal agreement as a fundamental criterion while trying to maintain a critical attitude about the reality of the external world, since other people are part of that world. My own opinion is that both are inferred from much more fundamental data.

[1] NATURE, **135**, 1035, June 22, 1935.
[2] "Scientific Inference", 1931.

DR. NORMAN CAMPBELL is so far right that in the philosophical interpretation of science conceptions about reality and existence lie at the very core of the matter. To me, these are primaries and indefinables. They can be explained only in terms of human practice; that is to say, again only in terms of the active side of reality and existence. The 'logical network' view cannot embody in its scheme this activist side of reality, for it is basically static and contemplative in character and purpose. A social philosophy of science, on the other hand, automatically makes man's capacity for changing the world an integral part of its story. The purpose of the philosophy is both conscious and dynamic.

It is for this reason that Mr. C. O. Bartrum[1] misses the point when he argues that the difference between the two views is merely one of words. The extent to which words may indeed arouse confusion is apparent when Mr. Bartrum quotes me as saying "that the man of science should be responsible for the social consequences of his work" and when he pictures the terrifying results that would follow in every laboratory if this were accepted. What I actually wrote was that my view keeps "the scientist alive to the social consequences". There is an ocean of difference between the two statements.

Origin of Man Again?

THE controversy on "Special Creation and Evolution"[1] continues to recur periodically in spite of the fact that it has long been known to scholars and learned Kabbalists that the Biblical narrative of *Genesis* is a representation of Chaldean allegories. To-day in many branches of science, writers can expound their knowledge for the uninitiated only by means of similes, metaphors and analogies; and yet it is still the practice to translate and interpret

ancient writings and glyphs literally and in terms of our present-day ideas, hypotheses and preconceptions.

Tentative theories and schools of thought are multiplying owing to the complexities revealed in recent years by researches in all departments. In a valuable summary of current opinions on the origin of species[2], Prof. J. Ritchie referred to "the minimum that different types of mind are prepared to allow in order to bridge the gulf of scientific analysis". It is evident that the synthetic function of the mind will not give birth to a new synthetic generalisation just yet; but the wider the search for an embryonic hypothesis the sooner will one be found that is workable and acceptable to the majority.

Evolution is a fundamental cosmic principle in all ancient philosophies; but it is conceived as a *dual process of involution and evolution operating in spiral cycles*. The creative energies of Nature are *serial emanations* or 'rays' symbolised by numbers, glyphs and geometrical ideographs. While the explanation of the evolution of species (*cf.* the *Purānas* and *Vedas*) is similar to the Darwinian theory of Western science, that given for the origin of man is different.

In "The Descent of Man"[3] there is a passage on hermaphrodite forms which shows how near Darwin came to postulating a primeval androgynous stem from which, according to ancient teachings, the mammals sprang.

Briefly, in the Eastern Aryan philosophy:

(1) Each *genus* has its own 'primordial' and distinctive 'form'; and these ethereal prototypes are gradually precipitated contemporaneously with the condensation of the globe.

(2) They had become semi-physical colloidal forms of bi-sexual animals in the early Secondary Age, and were fully consolidated physiologically, and sexually differentiated during the Jurassic period. Man preceded most of the mammals.

(3) The evolution of species, races and variations was subsequent to the complete physicalisation of the tenuous colloidal forms.

This 'hypothesis', of course, "simply pushes the problem back to"—another *state*! But the phenomena of 'periodical precipitation' and of colloidal states had not been investigated in Darwin's time. To-day we are accustomed to seek for 'causes' and 'origins' in imperceptible states.

Alchemy and Music

THE supposed connexion between alchemy and music is much older than the sources quoted by Prof. Read[1]. A treatise in the "Collection" of Greek alchemists[2] deals obscurely with this subject, and it has been the object of an interesting study by Prof. Stephanides, of Athens[3]. The ultimate source is, of course, the "Timaeus" of Plato, in which the compositions of materials are explained as due to mysterious 'harmonies'. Plato was in later life much influenced by Pythagorean schools, as has been shown by Frank[4]. He was obsessed by the idea that mathematics is in some way or other the ultimate reality, and that Nature must be explained by mathematical laws, or even Nature *is* these mathematical laws. In this he seems surprisingly 'modern', or rather, modern views seem surprisingly Platonic. Most of the ideas of later alchemy are merely more or less denatured versions of the theories of the Greek alchemists, and if the music was intended for performance during the practical operations this may also be an old ritual.

J. R. PARTINGTON.

Wembley.

THE lecture concerned dealt exclusively with certain aspects of seventeenth century alchemy, and Maier's musical compositions of 1618 may perhaps be taken as the last and most definite attempt to associate alchemy with music. Prof. Partington's early references are very interesting.

Breeding of *Loris* in Captivity

THERE is no record of *Loris* having been bred in captivity, so it seems worth recording that one was born in my collection recently.

This animal is well known to be difficult to keep alive in confinement, and in the hands of most persons who have kept them they live only two to three months. As the period of gestation appears to be longer than this, it is not surprising that breeding has not occurred, though several instances have been recorded[1] of babies having been born to females already pregnant at the time of their capture.

Upwards of fifty individuals of the genus have now passed through my hands, and I have been successful in keeping them alive in confinement for varying periods. Some still alive have been in captivity for more than two years. The Mysore loris (*L. tardigradus lydekkerianus*) appears to stand confinement better than the Ceylonese races.

In April 1934, on leaving Ceylon on furlough, I left my collection in the charge of Dr. L. Nicholls, Government bacteriologist. In one cage were a number of specimens of the loris *L. t. tardigradus*, and in the same month was added a full-grown male of the northern race, *L. t. nordicus*. I noticed that, at the time of handing over, all the males had their testes fully descended, whereas previously their scrota had been empty. The descent in some of the males took place over-night.

All the lowland lorises in the cage mentioned died in my absence, except one female. She was evidently impregnated by the northern male in the latter part of 1934. Dr. Nicholls informs me that no copulation was observed. A baby was born on April 24, 1935. I noticed a few days later that the father had his testes descended again.

It seems out of the question for the pregnancy to have occurred as a result of the rutting activities of the male in April 1934, as this would give a pregnancy of nearly a year. It seems much more likely that the male has a testicular descent twice a year as suggested by Narayan Rao[2], and that the pregnancy dated from a rutting season in or about September or October 1934.

Although the full evidence cannot be discussed here, it would seem that *Loris* in its breeding habits

differs from its nearest relative, *Nycticebus*, and also from *Tarsius*, both of which breed continuously, and agrees with *Lemur* in having a well-demarcated bi-annual breeding season[3]. It would also appear that the gestation period is somewhere in the neighbourhood of six months—a very long period for so small an animal. This time, however, is supported by the evidence of a very long lactation period as already reported by me[4].

Chemistry of Œstrogenetic Substances

As reported previously, unsaturated fat-aromatic α-ketonic acids injected into spayed mice give rise to the appearance of cornified cells in the vaginal smears[1]. Contrary to these results, J. W. Cook and E. C. Dodds failed to see an œstrogenetic effect with benzal-pyruvic acid and fural-pyruvic acid on spayed rats[2].

The total doses required for spayed mice are 24 mgm. dry sodium salts given in three doses at intervals of 24 hours. Cook and Dodds, working on rats, used doses of 100 mgm. (Calculated according to Parkes and Dodds[3], 240 mgm. would be the corresponding doses to produce œstrus in rats.) Their doses, therefore, were insufficient. Furthermore, they space the single injections of these substances in such a way that even a total amount, otherwise active, would be inactive under these conditions. "The importance of spacing the injections at the correct intervals cannot be over-emphasised." (Cook, Dodds *et al.*)[4]

The œstrogenetic effect of benzal-pyruvic acid and fural-pyruvic acid on spayed mice has been observed independently elsewhere. The statement that the œstrogenetic activity of unsaturated fat-aromatic α-ketonic acids is of the order of 1-keto-1.2.3.4.-tetrahydrophenanthrene is correct. It is known that figures of the same order are not necessarily identical figures.

Carotid Gland of the South African Bullfrog

THE physiological and histological studies of Heymans[1], de Castro[2], Koch[3] and others have clearly shown the great importance of the sinus caroticus in the control of circulation and respiration in mammals. The carotid nerve, which arborises in the adventitia of the sinus, is innervated by the internal pressure of the blood, and the heart-rate and respiration are reflexively affected.

Except perhaps for its absence in a few species, for example, *Ichthyophis*, the carotid gland is very characteristic of amphibians. It is also present in *Breviceps*, which never takes to water. It may therefore be profitable to study it in the light of the works on the carotid sinus in mammals.

The carotid gland of a full-grown *Pyxicephalus adspersus* is approximately 2·5 mm. in length and 1·5 mm. in breadth. Its size allows of macroscopic dissection, while on the other hand it is small enough to be fixed entire for histological dissection and staining. A series of longitudinal sections supplemented by a series of transverse sections show the following: Soon after its entrance into the swelling, the common carotid artery is seen to communicate by means of several openings with two fairly large vessels, which join and leave as the external carotid artery. The openings may also be seen in a longitudinal macroscopic dissection of the 'gland'. Somewhat deeper in the swelling, the lumen of the common carotid expands, but eventually breaks up into a network of arterioles. These again unite to form a flattened lumen, which, however, becomes more arterial and leaves as the internal carotid artery.

Several interesting points may be noted. Melanophores occur abundantly in the network, while groups of cells are distributed in it which are very reminiscent of nerve cell bodies. Silver staining will be resorted to in order to detect nerve fibres if present. Histologically the carotid gland is a very much elaborated artery. Compared with that of the sinus caroticus in mammals, its media is very thick and traversed by many elastic fibres. The carotid gland will therefore not allow of passive dilation to the extent that the sinus caroticus does. Constriction of the carotid glands in the etherised frog registered no notable change in the frequency of the heart-beat.

Suggestions as to the probable function of the carotid glands in the frog are reserved at this stage of the study.

Forces of Attraction of Homologous Loci and Chromosome Conjugation

A SERIES of genetic and cytological data show that chromosome conjugation at meiosis is caused by the attraction of homologous parts.

A study of chromosome behaviour in heterozygous inversions has disclosed with special clearness the action of these forces. We have obtained a stock of *Drosophila melanogaster* possessing attached *X*-chromosomes, one of which had an inversion involving almost the whole chromosome. If the forces of attraction of homologous loci are sufficiently great to overcome conjugational difficulties, which are connected with heterozygous inversions, chromosome conjugation ought to take place as in Fig. 1 (left hand). In this case ring chromosomes would form as a result of a single crossing-over in an inverted region. On the left end of the *X*-chromosome, these ring chromosomes would have a small deficiency and on the right one a duplication. The stock with

attached X-chromosomes obtained by us gave a progeny, part of which in fact contained a ring chromosome (Fig. 1 (right hand), Stern's culture $xy'\ y''$).

The frequency of single crossing-over (number of distal recombinations) had at the same time not decreased. Here, too, in all the one hundred per cent of ovocytes, the same as under normal conditions, the X-chromosome undergoes crossing-over and forms at least one chiasma.

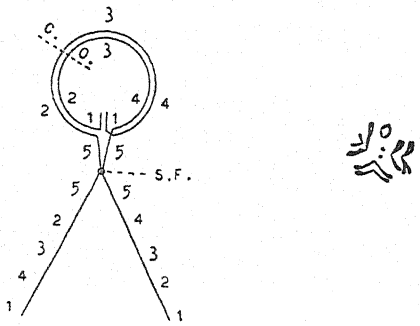

FIG. 1.

A study of double crossing-over in a similar heterozygous inversion sc^8 (non-attached X-chromosomes) has shown that the difference between the frequency of double cross-overs in a heterozygous inversion sc^8 and that of double crossing-over in a homozygous one, may be explained by the occurrence of new regional differences during ring conjugation. The increased percentage of non-disjunctional males and females which arise in a heterozygous inversion are a result of double crossing-over. Experiments show that the increase of double crossing-over in a heterozygous inversion causes an increase of the number of exceptional individuals. The presence of the latter cannot therefore prove the disturbance of chromosome conjugation.

The data obtained by us in this work indicate that in a heterozygous inversion of *Drosophila*, chromosome conjugation occurs in the same way as has been described by McClintock for *Zea Mays*. There the forces of attraction of homologous loci which bend the chromosome into a ring cause complete conjugation, notwithstanding the presence of an inversion in one of the chromosomes.

The existence of a *Drosophila* stock with attached X-chromosomes where ring chromosomes are permanently formed, is a new cytogenetic proof of Morgan's theory of crossing-over.

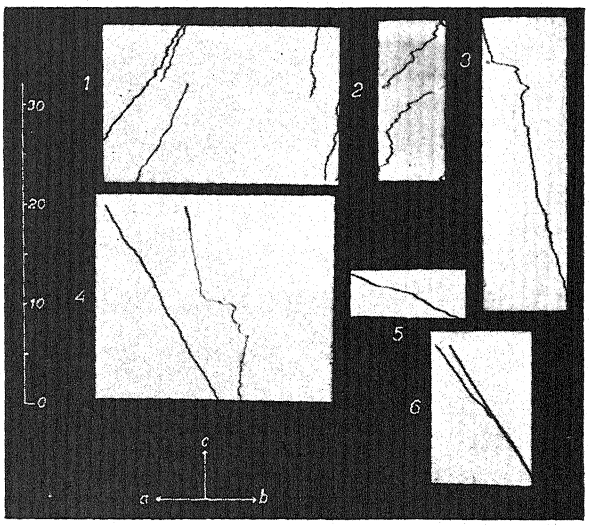
Cosmic Ray Bursts in Liquid Dielectrics

BURSTS of ionisation produced by cosmic rays have been studied up to now in large ionisation chambers filled with a gas at high pressure. We found it advantageous to use for this purpose ionisation chambers filled with a very carefully purified liquid dielectric.

A series of preliminary observations was made with the use of a cylindrical condenser having a capacity of nearly 1 litre containing hexane (C_6H_{14}); the interior armature was an empty cylindrical vessel. The conductivity of the hexane was as low as $2{\cdot}3 \times 10^{-19}\ \Omega^{-1}$ cm.$^{-1}$. In most cases a difference of potential of 1,800 volts was applied; such a considerable field was necessary in view of the small mobility of ions in a dielectric liquid (mean value in hexane[1] is 5×10^{-4} cm./sec. per cm./volt).

The armature receiving the charge was connected with a quadrant electrometer of common pattern. It recorded the gradual charging of the system by the spontaneous current in the liquid. Bronson resistance was used for compensating this current. Bursts provoked sudden deviations of the electrometer needle and corresponding displacements on the curve of the record. It was possible easily to recognise bursts supplying more than 3×10^6 ions (the actual number of ions produced was considerably greater in consequence of the loss by recombination).



To characterise the phenomenon we give two numerical results and reproductions of some records obtained[2]. In an unprotected ionisation chamber, the number of bursts was 2 in 11·7 hours. In the most favourable case, the chamber surrounded by lead blocks 5 cm. thick and the aluminium cylinder put into the interior armature, the number of bursts increased to 37 in 13 hours.

In the accompanying illustration are reproduced the records of some typical bursts: Nos. 1, 2, 3 are simple bursts; Nos. 4, 5 seem to be double bursts; No. 6 is of more complicated structure. The arrows indicate directions of deviations of the electrometer needle due to (a) compensating currents, (b) residual, and (c) the direction of movement of the sensitive film. On the left is a time-scale in minutes, which enables a rough estimate to be made of the duration of the bursts.

[1] One of us has recently made a detailed study of the mobility of ions in liquid paraffins: I. Adamczewski, *Bull. Int. Acad. Polonaise*, 217; 1934. The existence in these liquids of three sorts of ions of different mobilities was discovered.

[2] More details will be given in a paper appearing in a forthcoming issue of *Bull. Int. Acad. Polonaise*.

Electrical Units and the I.E.C.

PROF. E. W. MARCHANT, who was one of the British representatives at the recent meeting of the I.E.C. at Brussels, has sent me an account of the proceedings in connexion with the proposed introduction of the M.K.S. system, which he authorises me to publish. I should be greatly obliged if space could be found for it in NATURE.

R. T. GLAZEBROOK.

Laboratories of Applied Electricity,
University of Liverpool.
July 9, 1935.

DEAR SIR RICHARD GLAZEBROOK,

Dr. Rayner has written to me regarding the meetings of the E.M.M.U. at Scheveningen. It was agreed that the M.K.S. system should have units which were consistent with the C.G.S. system, and all the representatives of the different countries agreed that it was very desirable that the present practical system should be extended so as to make it a coherent system of units. When the matter came up for discussion at the Committee of E.M.M.U., the question under discussion was divided into two. The first was concerned solely with the desirability of a coherent M.K.S. system without specifying the fourth unit, and the second with the choice of the fourth fundamental unit. On the first question, all the members declared themselves in favour of the adoption of an M.K.S. system with four fundamental units, except the representative of Norway, who abstained. On the second question, the Committee decided to consult, on one hand the Consultative Committee of the B.I.P.M., and on the other hand, the S.U.N. Dr. Lombardi was asked to prepare the question to submit to the Consultative Committee of the B.I.P.M., and Dr. Kennelly to prepare that to be submitted to the S.U.N. Although there is nothing in the minutes of the proceedings stating that the basis of the decision regarding the fourth unit should be that the permeability of free space should be taken as unity, that point was repeatedly raised in the discussion, and the way in which the matter was left, was that the committees to be consulted should be asked to give a value for the fourth unit which was consistent with the value of the permeability of free space being equal to unity.

It was agreed by everyone that the fourth unit to be adopted (either a unit of quantity of electricity or a unit of resistance) must be consistent with the C.G.S. system of units, and the reason why the question of the fourth unit was referred to the two committees concerned, was that the Commission was anxious that whatever unit was chosen should be consistent with the C.G.S. system of units.

Yours very truly,

E. W. MARCHANT.

Points from Foregoing Letters

DR. J. K. MARSH and Prof. S. Sugden describe and tabulate results obtained by bombarding rare earth elements with neutrons. Radioactivity of varying intensities, with half-life from a few minutes to two days, was produced in nine out of thirteen elements. Europium, dysprosium and holmium were found particularly active; it is suggested that these elements may be useful as neutron detectors. Prof. G. Hevesy and Miss Hilde Levi give a similar table for the radioactivity induced in eleven rare earth elements. The two tables are not in entire agreement, owing, as both groups of investigators point out, to the difficulty of obtaining the rare earths in a pure state. Neodymium and gadolinium, the activity of which is given as zero by Marsh and Sugden, are said, by Hevesy and Levi, to have a slight activity; the values for the intensity and half-life in the case of several other elements also differ in the two tables.

The rate at which molecules of heavy hydrogen gas are exchanged for the hydrogen atoms of water molecules in a suspension containing lactic acid bacteria varies with pressure, the velocity constant being inversely proportional to the square root of the pressure, according to Messrs. G. H. Bottomley, B. Cavanagh and M. Polanyi. The active catalytic agent is an enzyme equally active whether the bacteria are dead or alive.

M. A. Pérard describes the methods employed in determining the length of the national prototypes of the standard metre, and concludes that in spite of the raggedness of one of the fiduciary lines, an accuracy of 0·2 microns is possible. Dr. W. E. Williams emphasises the fact that accuracy would be greater if an optical gauge were used in place of the line standard. He still believes it possible that a discrepancy of 0·56 microns in the length of the British and German standards may exist.

F. Watson, Jr., reviews critically theories dealing with the origin of tektites, which are small glassy particles of lens-like, pear or dumb-bell shape, found at various places on the earth's surface. He concludes that no satisfactory meteoric theory of their origin is as yet available.

Prof. W. C. O. Hill records that a specimen of loris, one of the Indo-Malayan lemurs, was born in captivity in Colombo, and describes the breeding habits and period of gestation of the species.

A histological study of the carotid swelling in the South African bullfrog, *Pyxicephalus adspersus*, by Dr. G. Eloff, has shown that it is a much elaborated artery with a relatively thick media. Before the internal carotid artery leaves the swelling, the common carotid breaks up into a *rete mirabile*, in which melanophores occur abundantly, and probably also nerve-cells. Constriction of the carotid swellings did not affect the heart-rate.

The formation of a loop during the conjugation of heterozygous chromosomes (derived from unlike parents) of the fruit-fly, *Drosophila melanogaster*, during fertilisation is described and illustrated by Messrs. B. N. Sidorov, N. N. Sokolov and I. E. Trofimov. In order that homologous portions of the chromosomes may lie side by side notwithstanding the presence of an inversion in the order of the genes in one of the chromosomes, a 'loop' is formed as a result of a single crossing-over in an inverted region.

Prof. C. Białobrzeski and I. Adamczewski have found that the use of liquid dielectrics is advantageous for the study of the cosmic ray bursts. In an ionisation chamber of 1 litre capacity filled with carefully purified hexane, they observed 37 bursts in 13 hours. Several bursts are double or even of more complicated structure.

Research Items

Origin of the Domesticated Horse

IN a survey of the evidence bearing on the evolution of the modern domesticated horse, Dr. Max Hilzheimer (*Antiquity*, 1935, June) confirms the surprising inference from the bones found in the Royal Tombs at Ur that the early Sumerians had domesticated the Asiatic dziggetai or onager. Bones since found at Tell Asmar include numerous remains of the onager, but none of animals resembling the horse. There are two, possibly three, varieties of the early horse. It is represented in palæolithic art; but it was not domesticated until neolithic, and in places, bronze age times. Its habitat was north of the central Eur-Asiatic mountain chain, except for Spain, and extended from western Europe to Mongolia. Of the two varieties, the Tarpan lies west of long. 40°, Przewalski's horse to the east. An early classification divided the domesticated horse into an oriental and an occidental breed, contrasted as in the Arab and the Clydesdale; but an early breed indigenous to Europe and native to Poland is the Konink. Notwithstanding opinion to the contrary, the original home of the Arab or oriental type is Europe, its distinguishing characters being due to climate and careful breeding. The earliest representations appear on the monuments of Assyria dating to the first half of the first millennium B.C., though it had been introduced there long before by Aryan tribes. In varying form this is the horse of the Egyptians, Hittites, Greeks, Romans and Scythians. The so-called occidental horse has been thought to be descended from the prehistoric horse, of which remains are found in the glacial deposits of Central Europe; but the break in continuity precludes this view. It first appears in dual form as the Noric horse and the horse of Persepolis of the fifth or sixth century B.C. The heavy draught horse is first seen on a tombstone at Chalon-sur-Saône in the second century B.C., and there can be little doubt that, like the Arab type, it was a product of breeding and climate which appeared first in the countries, broadly, bordering on the North Sea.

The Tongue

PROF. DAVID KATZ, formerly of Rostock University, has communicated to the Manchester Literary and Philosophical Society a summary of the results of his research on the tongue as a primitive sense organ (*Mem. Manchester Lit. and Phil. Soc.*, 1933–34). All theories of evolution, however much they may differ, agree that life must have originated and developed in water and later adapted itself to conditions on dry land and in the air. Psychologically, this is manifested in the strength of our need of water. The function of perceiving wetness seems to be restricted to one organ, the tongue. The sense of taste is a specific chemical sense; and it is a near-sense as it has to have contact with the chemical stimulus without the intervention of a medium. It cannot taste solids; they must be dissolved, this being the function of the saliva. The tongue is also remarkably sensitive to an electric current. With regard to the sensations of wetness and dryness, while all the external surface of the body is dry, the internal surfaces are moist. Normally, neither wetness nor dryness is felt in a specific manner. The only part of the body which gives a real subjective impression of wetness is the tongue, while the pharynx gives a nearly permanent impression of dryness. Together they probably form a single sensory unit which as a whole plays an important part in supervising the water economy of the body. The sensation of dryness in the pharynx controls the secretion and swallowing of the saliva. With regard to electric taste, a series of experiments has shown that an opposition of taste is created at anode and cathode of sour-salty and bitter-sweet, which can also be described as relatively bright and dark or heavy and light in analogy with the impressions of other senses, while other, tingling sensations are experienced which probably represent the generation of gas. These impressions do not depend on the metal used, and whatever the combination the threshold appears at the same intensity of current.

Ecological Conditions in Coffee Plantations

UNDER the title of "The Climate and Eco-climates of Coffee Plantations" by Mr. T. W. Kirkpatrick, entomologist, East African Research Station, Amani, Tanganyika, there has recently appeared a memoir interesting to entomologists and botanists alike. The investigations concerned were undertaken in coffee plantations in Kenya Colony. After discussing the standard climate of the district concerned, the author deals with the air temperature at a height of 1·3 metres between the rows of coffee bushes, and compares it with that in the standard screen. Similar temperatures inside a coffee bush are also recorded, together with the temperatures of the leaves of such a bush and the body temperature of an insect (*Antestia*) on the surface of a bush. Soil temperatures, humidity, precipitation, evaporation, light and other factors are dealt with in detail. The author then goes on to discuss the various factors which modify the climate of a coffee plantation. It was found that, in general, the climatic conditions in a plantation differ widely from those which obtain in a standard meteorological screen, and do not always vary in the direction which might be anticipated. It is possible, however, to deduce, with fair accuracy, the extent to which these conditions will vary from a standard. The author describes the technique employed, and the data obtained, in detail. The work is an important original contribution which should be read by all ecologists and may be obtained, price 5*s*., post paid, from the Research Station at Amani, or from the Crown Agents for the Colonies, 4 Millbank, S.W.1.

A Cure for Lime-induced Chlorosis of Fruit Trees

A yellowing of the foliage of apples and pears, induced by lime, causes a considerable amount of damage in some fruit-growing areas. Dr. T. Wallace, of the Long Ashton Research Station, has shown that this state can be remedied by the simple expedient of allowing grass to grow between the trees. This is not always desirable, however, and in a recent paper he gives the results of his experiments with a new method of treatment (*J. Pomol. and Hort. Sci.*, **13**,

No. 1, March 1935). The method is very simple. Holes are bored in the trunk with a brace and bit, a small quantity of ferrous or ferric citrate is placed within, and each hole is then closed with a cork. Treatment by this method has been quite successful, and has converted failing trees into healthy specimens. It only remains to investigate the duration of the treatment over a period of years.

Encroachment of the Sahara

IN a paper in the *Geographical Journal* of June, Prof. E. P. Stebbing directs attention to the serious threat to the West African colonies of Great Britain and France by the encroachment of the Sahara. This is due, not to climatic causes, but to the methods of agriculture pursued. Shifting cultivation is still the practice. A piece of forest is felled, the timber burnt and the ground is sown and ultimately harvested. When the weeds become too heavy, or the yield inadequate, the patch is abandoned and a new one occupied. Thus the deciduous forest on the verge of the Sudan becomes degraded, more open and drier. Eventually savannah supervenes, which in West Africa is a term applied to bush or scrub. Herds of the nomadic shepherds then occupy and further destroy it. When its fodder value has almost gone, the herdsman cuts the scrub trees to get fodder for the goat. This is the last stage in the ruination of the land and the advance of the desert. Prof. Stebbing traces the degradation of the forest with the associated ruin of the land in a broad belt in Nigeria and elsewhere, and strongly advocates the need of reserving a belt of degraded forest at least some fifteen miles in width and more than 1,300 miles in length, in which tree growth could be improved and further destruction checked. Thus the advance of the Sahara might be stopped.

Old Maps of Wales

A USEFUL account of the maps of Wales up to A.D. 1600 is published by the National Museum of Wales ("The Map of Wales". By Dr. F. J. North. 1*s*.). Apart from diagrammatic representations on the Peutinger Table, Ptolemy's maps and medieval mappae mundi and portolan charts, there was no map of value until the latter part of the sixteenth century, when there were published the Mercator map, the Lhuyd map and, most notable, the Saxton map. These are fully discussed. But of equal interest is the anonymous fourteenth century map known as the Gough map in the Bodleian library. Its date is uncertain but probably so early as 1340. The volume contains representations of parts of many of the early maps.

Atomic Weight of Terbium

THE isotopic composition and atomic weights of the rare earth elements as determined by F. W. Aston (*Proc. Roy. Soc.*, **146**, 46; 1934) are sometimes in marked discrepancy with the chemical values. In the case of terbium, the values are 158·91 (Aston) and 159·2 (international value). A volumetric determination of the atomic weight of terbium, with very pure material prepared by the fractionation of the dimethylphosphate, has been made by J. K. Marsh (*J. Chem. Soc.*, 772; 1935). The oxalate was prepared and the ratio $Tb_2O_3 : 3C_2O_3$ was determined by ignition and by titration with permanganate. The value derived for the atomic weight was 158·9. This assumes the atomic weight of carbon to be 12·00, but if it were raised to 12·01, the value for terbium would be raised only to 158·92. The new value, for which accuracy in the first place of decimals is claimed, is in very good agreement with that found by Aston, and hence both the chemical and mass-spectrograph methods indicate a value 158·9 for the atomic weight of terbium.

Structure of Cupric Compounds

E. G. Cox and K. C. Webster (*J. Chem. Soc.*, 731; 1935) have examined by means of X-rays the structures of some quadricovalent compounds of bivalent copper containing acetylacetone, benzoylacetone, dipropionylmethane and 3-chloroacetylacetone as addendæ. A complete determination of crystalline structure of such compounds would be very laborious, but a consideration of space-group results, cell dimensions and optical properties shows clearly that the molecules are planar, that is, the four valencies attached to the copper lie in one plane and are not tetrahedral. Since compounds in which a planar distribution has been established appear to be in no way exceptional, it is reasonable to infer that the planar configuration is normal for four-co-ordinated compounds of bivalent copper. This result, which confirms the view expressed by Werner, is not in accord with the conclusions of Mills and Gott in 1926, who obtained a strychnine salt of cupribenzoylpyruvic acid showing a small but definite mutarotation, and inferred that the valency arrangement was tetrahedral. The case for optical activity, however, rested only on analogy with the behaviour of the brucine salt of the corresponding beryllium complex. Since there is no doubt as to the tetrahedral configuration of beryllium, it seems that this analogy is false, and that the observed results of Mills and Gott were due to some cause other than a tetrahedral copper atom. According to Pauling, a planar configuration is to be expected when *s*, *p* and *d* electrons are involved in the valency bonds. It is possible, therefore, that bivalent copper possesses a complete 3_3 sub-group of ten electrons, some being shared, instead of an incomplete group of nine, as is usually supposed. This would involve one unpaired electron in the fourth principal quantum level, giving rise to a paramagnetic moment of the same order as that which has been found.

Nova Herculis

DR. A. BEER has published (*Mon. Not. R.A.S.*, **95**, 538) a light curve of Nova Herculis from the time of its discovery (December 12, 1934) up to April 3, 1935. This is based on visual or photometric measures by numerous observers and shows well the main features of the changes observed, including the steep rise just after discovery, the rapid fluctuations with a very slow average decrease, until the final spectacular drop of more than five magnitudes within a few days. The more recent recovery from the thirteenth to the eighth magnitude is not covered by the range of dates discussed. Measures of the spectra taken at Cambridge on these dates with the 15-in. Huggins refractor over the visual region from $H\beta$ to a little beyond $H\alpha$ (7331 A.) are included. About 150 emission lines or bands have been measured in this region, for the majority of which probable identifications are given, with the origins of other possible blending lines. Laboratory intensities and multiplet classifications are given for all the origins suggested.

Excavations at Tell Duweir, 1934-35

EXCAVATIONS at Tell Duweir, the Biblical Lachish, in the third season of the Wellcome Archæological Research Expedition to the Near East, of which Mr. J. L. Starkey is director, carried on the further exploration and clearance of the cave-dwelling settlement of the Early Copper Age which lies to the north-west from the Tell, the clearing of the temple and shrine outside the city walls at the north-west corner of the Tell, which was discovered last year and then shown to be contemporary with the xviii and xixth Dynasties of Egypt, the completion of the examination of the Iron Age cemetery to the south-west, the further clearance of the gate at the south-west corner of the Tell, with its subsidiary works, and further work on the summit of the mound, which included the clearing of the Persian shrine of the Sun. A considerable amount of labour was also expended on retaining walls for terracing the west side of the Tell and other necessary work for the disposal of the material to be removed in the course of excavation.

The season's finds have more than justified expectations based upon estimates of the importance of the site, apart from its size; and interesting as were the finds of last year, especially the discovery of the shrine with its associated examples of a localised art, reminiscent of Tell el-Amarna, and the fragments of the ewer inscribed with a primitive script showing affinities with the famous Sinai script, the results of the season recently closed show no falling off in interest. Indeed in certain respects, more particularly in the importance and the immediate applicability of the epigraphic material to Biblical studies, they may even be said to transcend previous discoveries. In addition, the epigraphic material has provided direct documentary evidence confirming the identification of Tell Duweir with Lachish.

The evidence which comes from the area to the north-west of the Tell, including what has been termed the prehistoric suburb, continues to point to a surprisingly extensive settlement and relative density of early prehistoric population. Further excavation in the cave-dwelling area of the æneolithic period has produced additional examples of the characteristic red ware in a variety of forms. One remarkable example is a very large jar, approaching a metre in height, which now has been reconstructed. It shows the peculiar feature of a vertical fissure or gap, of which the worn edges point to the use of the jar in two separate halves for some considerable time. With a number of carefully and beautifully formed flint knives, hoes and sickle blades with serrated edge were implements of pure copper. Of these last one was a remarkably well-preserved copper dagger, which had been beaten to a high degree of hardness and is among the earliest known from Palestine.

On the whole, the pottery of the Copper Age is at its best in the earliest period. In common with other elements in the culture, it shows a progressive deterioration as time goes on. One example of such degeneration, to which attention was especially directed in the collection of pottery dating from 3000–2000 B.C. shown at the Wellcome Research Institution, was to be seen in the form of the characteristic ledge-handles on either side of certain types of vessel. Throughout the period, from about 2800 B.C. onward, these dwindle away until they become the merest vestigial trace without apparent meaning. An interesting suggestion as to the purpose of these remarkable, if characteristic, ledge-handles has been put forward by Mr. Starkey, who thinks that they may have served as a grip to enable solid sediment, such as that which would be left by beer, to be shaken from the vessel.

In clearing the temple and shrine lying outside the walls at the north-west, evidence was found, strange to say, of a degradation somewhat similar in character to that deduced from the finds of the Copper Age. Three temples had been erected on the site. Between the erection of the earliest before 1400 B.C. and the destruction of the third in 1260 B.C., there is a progressive decline in the character of the temple and in material employed in the shrine and its appointments. It will be remembered that one of the most remarkable features of this discovery, apart from the character of the shrine as a whole, were the ivory carvings and carved inlays, which in style recalled the art of Tell el-Amarna, but were attributed to a local school of art. While the main characteristics of the cult appear to be constant, the inlays first change to bone, copying, but in a debased form, their ivory originals, and then, in the period of the third temple, clay figures appear. In like manner, in the last phase, the probable portable altar of the second shrine becomes a solid structure of brick, and the shrine itself is but mud lime-plastered.

Ivory rods of unknown use also appear in shortened form in clay. It has been suggested, however, that clay, which could be heated, would be a more suitable material, if these rods were, as conjectured, used for making the closely curled ringlets in hair and beard which adorn the inhabitants of Palestine in the Assyrian bas-reliefs.

Among the tombs of the Early Iron Age, or Solomonic period, an outstanding find was one which, there is reasonable ground for concluding, contained the mortal remains of a priest or minor official of the temple. This conclusion rests on the evidence of a remarkable three-pronged fork or trident of iron which lay at the entrance. It is some two feet in length and has a short handle. Its form immediately suggests a "flesh hook" for lifting meat from an offerings bin, such as that to which reference is made in *Samuel* I, ii, 13–14. Associated with this burial was an interesting collection of beads and a small ivory tablet, in which thirty holes in three vertical columns may have served as a memorandum or calendar to mark the feast days of a thirty-day month.

Before dealing with the finds which follow here in strict chronological order, a brief reference must suffice for the finds of the Persian period from the shrine of the Sun God. Among these were equally striking zoomorphic figures in clay and some of which were remarkable miniature altars of stone, on which animals, crude engraved designs of men, trees and animals.

What is beyond question the most important historical, discovery of the season is epigraphic and of interest. A rather than purely archæological in same primitive fragment of pottery inscribed in the the fragmentary script as that of the inscription on

ewer found last year has added three characters to those previously known. Even more important, however, to the historian and Biblical student, is a series of letters which belongs to the period immediately before the destruction of the city by Nebuchadnezzar in 598 B.C. The letters, mostly complete, and in some instances running to some length, are on seventeen ostraka which were found among the debris of the guard-room of the gate giving access to the fortress at the south-western corner of the Tell. They are written in ink in an early form of Hebrew, and according to a decipherment and translation made by Prof. Harry Torczyner, of the University of Jerusalem, were addressed to the commander of the garrison of Lachish from a subordinate command. One letter is much concerned with the observation of signals and suggests that it refers to a system of smoke signals by which communications were maintained between Lachish and the supreme command. This letter also refers to Lachish by name.

In a list of names of individuals in the correspondence a form compounded with *yahu*—a form of invocation of Yahweh (Jehovah)—predominates; but one among the names of the fathers of the individuals cited is given, not as a yahu compound, but as an El-compound (El-Natan). This points to a change from El to Yahweh worship within the lives of father and son, probably a result, it is suggested, of the reforms of Josiah. Of even greater interest to Biblical scholars is a reference to a prophet who had been the cause of disturbance, and the passing of a commander-in-chief, Akhboryahu, son of El-Natan, on his way to Egypt, which is clearly a reference to persons and incidents mentioned in *Jeremiah* xxvi, 20–22.

Scientific Management

THE papers given at the Sixth International Congress for Scientific Management held in London during the past week have been available in print for members since early in May (Secretary of the Congress, 21 Tothill Street, London, S.W.1). They are published in six volumes corresponding with the six sections of the Congress and are grouped under subject headings relating to the particular themes to be considered at the four sessions held by each section. Nearly all the 200 papers have a certain scientific interest, so that any selection from them is difficult.

Dealing with the subject of preliminary education for management, Mr. A. P. M. Fleming points out that at present provision is seldom made in industrial concerns to ensure continuity of good management beyond a single generation. The methods of selection of staff are discussed by competent authorities from the German, French, British, Dutch, Italian and Swiss points of view, so that a comprehensive picture of modern thought on this subject is available. When summarised, the information should be of great importance to educational advisers who have to help to place young men in life.

Opinion is hardening in business circles that the entrants from school should receive a good deal more vocational training than at present. The recruitment of personnel suitable for high administrative positions is likewise discussed in several papers. The National Institute of Industrial Psychology is responsible for a communication which deals with the vexed question of promotion versus engagement from outside on the basis of the experience gained by the Institute, and schemes are put forward showing how to discover men within a company for training and how to select from outside. The Dutch authors regard personnel selection as a profession in itself: the Italians would invoke a psychotechnical criterion.

It is widely said that there is a shortage of men to-day for the senior posts, probably because of the toll taken by the War of the more enterprising. It is clear that there is world-wide concern with regard to leadership; hence the numerous suggestions as to the form of training. The volume containing the educational and training section papers deserves to be read as a whole both by executives who have the choice of their successors and by the educationists.

In the development section the bulk of the papers discuss the correct methods of inculcating modern management principles and practices. They come from many lands and cover a variety of problems. Thus C. G. Renold describes the steps taken in the merging and subsequent rationalisation of a group of companies employing 5,000 people; he attempts to assess the costs involved and the benefits resulting: this is a most valuable contribution. H. J. Mitchell discusses the methods adopted by Imperial Chemical Industries, Ltd., of which he is a leading director, in the management of its many activities, the general desire being to have a stable organisation where stability is essential but a high degree of flexibility in other directions where research and development require it. Whereas management of the groups is decentralised, finance is fully centralised. The Company's whole-time directors are relieved of direct executive duties, and a considerable amount of authority and responsibility is delegated. This account of the management of our largest undertaking contrasts with one, describing the methods used in a small tapestry factory, which follows it.

The account of the I.C.I. scheme of management will be widely studied, the more so as it is realised both that the problem of the successful management of so large an organisation is one of very great difficulty and that the difficulties have been largely overcome by I.C.I. along the lines outlined.

A second series of papers in this volume deals with the rôle of institutions, trade and other associations in relation to management problems. A thoughtful summary contributed by a committee representing the Federation of British Industries analyses the association movement as affecting efficiency, and makes some constructive suggestions as to the manner in which trade associations can be of assistance.

In the manufacturing section the subject of budgetary control attracts first notice. An important review representing the accumulated experience of some of the leading firms in Great Britain is contributed by Roland Dunkerley. The idea indicated by the term is to substitute considered intention for opportunism in business; it has been much discussed and studied during recent years, and the theories of

such control are firmly established and widely known. Its application is proving increasingly successful though it is necessary to adjust the principles to meet the varying demands of the various industries.

A second group of papers deals with scientific methods applied to works management in a number of specific examples.

Distribution is becoming very definitely a science. It is axiomatic that the manufacturer of a new product must sell it and that the true market is always the ultimate user. A paper contributed by the Advertising Association of Great Britain gives a particularly good summary of the routes through which a new product can be distributed to the public, with concrete examples of recent introductions. Any reader of this volume who has the task of introducing a new product can easily ascertain the international views as to how he should begin his task. Large organisations are finding it worth while to establish special departments for marketing research: some of the methods employed and results obtained in the United States are described by Mr. O. F. Roost. As one industry after another reaches a point where it is able to produce more than the market can apparently consume, competition becomes keener and the need for more intimate and accurate knowledge of existing markets and possible new ones becomes apparent. E. F. A.

The Metallic State

A CONFERENCE on "The Metallic State" was held in the University of Bristol at the H. H. Wills Physics Laboratory on July 2–5, about forty visitors being present from other parts of England and from the Continent. Most of the visitors were housed in Wills Hall, one of the University halls of residence.

At the opening session of the Conference, Dr. J. A. Prins (Groningen) gave an account of the results obtained at the University of Groningen on the absorption and emission of X-rays by metals. The absorption spectrum in crystalline solids has a fine structure extending several hundred electron volts on the short wave-length side of the edge, and depending in its general features only on the structure, and not on the atomic constitution of the crystal. A theoretical explanation due to Kronig was discussed, which relates the phenomenon to the Bragg reflection of the ejected electrons. Dr. H. W. B. Skinner (Bristol) showed how the study of emission bands in the ultra-soft region can give information about the occupied electronic states in metals. Prof. W. L. Bragg (Manchester) gave a report of some recent results obtained by Sykes on the formation of a superstructure in copper-gold alloys, and Mr. J. D. Bernal (Cambridge) discussed the factors which determine the crystal structure of alloys, pointing out especially that the atomic radii of the constituents have often a decisive influence.

The morning of July 3 was devoted to a discussion of the liquid and amorphous states. Prof. H. Mark (Vienna) gave an account of recent theories of electrical conductivity, and Dr. J. A. Prins gave a report on his own work on amorphous antimony. Dr. G. W. Brindley (Leeds) showed the effect of filing on the intensity of X-ray reflection from metals. In the afternoon there was a discussion on the properties of metallic bismuth, in which Prof. A. Goetz (Pasadena), Dr. N. Thompson (Bristol), Dr. D. Shoenberg (Cambridge) and Dr. H. Jones (Bristol) took part. Bismuth is peculiar in that very small quantities (less than 0·1 per cent) of lead, tin or other metals in solid solution have a very marked effect on its electrical conductivity and diamagnetic susceptibility. Prof. Goetz expressed the opinion that these facts suggest the existence in bismuth of a microcrystalline superstructure of the kind postulated by Zwicky, but an alternative explanation was suggested in terms of the wave mechanical theories due to Peierls and Jones. These theories, however, will require further development before any quantitative account of the facts can be given.

On July 4, Prof. W. Gerlach (Munich) gave an account of the work carried out in his laboratory on the electrical resistance of nickel and of some of its alloys. The resistance of nickel decreases in a magnetic field, the decrease being proportional to the change in σ^2, where σ is the magnetisation. Further, the resistance plotted against temperature shows a kink at the Curie point. A possible explanation of the effect was suggested by Prof. N. F. Mott (Bristol). Dr. E. C. Stoner (Leeds) pointed out that various methods of determining the Weiss intramolecular field constant in nickel give very discordant results, and suggested an explanation.

On July 5, a discussion on supra-conductivity was opened by Dr. J. M. Casimir (Leyden), who gave an account of the fundamental experiments of Meissner, and of de Haas and Mrs. Casimir, and of the important theoretical advances of Gorter, Casimir and London. Mr. K. Mendelssohn (Oxford) gave an account of the behaviour of certain alloys. It appears that though great progress has been made towards the understanding of the thermodynamics and electrodynamics of a supra-conductor, we are still as far as ever from knowing the cause of the phenomenon. Dr. H. Niewodniczański and Mr. C. J. Milner (Mond Laboratory, Cambridge) discussed the electrical conductivity of non-supra-conductors, and here also the results of theory are by no means in accord with experiment, and the opinion was expressed on several sides that all theories are wrong below 4° K. Prof. F. Simon (Oxford) and Dr. E. Teller (London) also discussed the possibility of using nuclear spins to obtain yet lower temperatures than can be obtained with ordinary paramagnetics by the magnetic cooling method.

An interesting feature of the Conference was the frequent mention of experimental facts for which no quantitative theoretical explanation could be given. Considerable advances have recently been made in the quantum theory of the metallic state, and it is now possible for the theorist to give an indication of why certain metals have their particular crystal structures, magnetic properties and electrical conductivities. Nevertheless, the theory is as yet far from being able to give such a complete account of the experimental data as is possible, for example, in the field of atomic spectra.

Biology at the Imperial Social Hygiene Congress

AT the recent Congress held under the auspices of the British Social Hygiene Council at the London School of Hygiene and Tropical Medicine, the teaching of biology formed the main topic of the papers read during the educational sessions. It is satisfactory to hear from Dr. E. W. Shann that it is now realised that there are two categories of pupils to be considered in the drafting of syllabuses, namely, those for whom biology is a necessary part of their general education, and those who require it for vocational reasons. Up to an early stage, the needs of these two may be regarded as identical; and they will probably be met by a well-balanced course of general elementary science in which hygiene and the functions of the chief organs of the human body should certainly be included. The scheme advocated by Mrs. E. J. Hatfield, which is already in use in many girls' schools, and deserves the attention of others where the ages of pupils permit is: Age 11–12 years, general elementary science; age 12–14 years, chemistry, or chemistry and physics; age 14–16 years, general biology, and in addition, chemistry or physics for future science specialists.

For purposes of general education, biology is unquestionably preferable to either zoology or botany; and that this is becoming more widely recognised by teachers is shown by the steady increase in the number of candidates offering biology at certificate examinations, and the corresponding diminution in that of those offering either of the other subjects. A knowledge of the structure and life-histories of a few typical animals and plants does not bestow on its possessor a biological outlook on the world around him and on the problems of mankind: the type system is dead so far as general education is concerned. It is biological topics rather than types that will eventually produce a biologically minded public, and, it is to be hoped, lead to social legislative measures based on the conviction that man is subject to the same laws of Nature as are all other animals.

The topics that are essential in such a course are (1) food elaboration by green plants, the source of all vital energy and conversions of energy; here is abundant opportunity for personal experimental work, even on the large scale, in rural schools possessing gardens; (2) the structure of a mammal, and the functions of the chief organs; (3) reproduction, asexual and sexual, in plants and animals; parental care, and its importance in evolution; (4) the web of life, and mutual interdependence; heredity; evolution; biology in the service of man; (5) bacteria and fungi, and their rôle in the nitrogen- and carbon-cycles.

It is obvious that mammalian physiology will be human; nor is any apology for this necessary. A child is naturally and properly curious about the workings of its own body, and most children are keenly interested in living animals, and perhaps also in growing plants. Thus it becomes easy and not inappropriate to digress from the processes going on in the body of the living child to the methods by which the same processes are effected in other animals and in plants. For example, human respiration may well be followed by the methods of respiration found in, say, fish, snails and insects, and by demonstration of the fact that in plants respiration is essentially the same as in animals. Similar digressions can be made in connexion with all the other metabolic processes, which need not here be specified. In such a course, instruction on the details of structure would be reduced to the barest minimum; morphology is for the specialist, not for the general public; and the topics would be purely biological, and freed from the type incubus.

It is generally conceded that biological teaching is the best method of instructing in the laws of health and in the meaning of sex. Indeed, in some quarters sex-instruction has been the chief reason for advocating the inclusion of biology in all school curricula. Certainly knowledge of the sexual processes in plants and in the lower animals affords an avenue by which approach may be made to the relation of male and female in the human species; but to stress this aspect in a course of general biology is a mistake; the functions of the reproductive system should have neither more nor less attention devoted to them than is given to those of the digestive, respiratory, excretory and the rest.

What matters most is that for all the processes of life there should be instilled a respect, a reverence for the mystery of life, an appreciation of the beauty of the form of living things and of their marvellous adaptations to their environment. Knowledge without the spirit of reverence will not have much influence on the moral conduct of man or of woman.

It is, then, very desirable that training colleges should emphasise this aspect of biology, and should insist on this subject being included in the science course; for the lack of qualified teachers has not yet been made good.

The Museums Association

ANNUAL CONFERENCE AT BRUSSELS

THE Museums Association, which has its headquarters in London, and holds its annual conference at different provincial centres in turn, this year departed from its usual custom, and, at the invitation of the Belgian Government, held its Conference in Brussels, where more than two hundred members assembled.

After the Sunday had been spent in visiting the city and its museums, formal proceedings began on Monday, July 1, when members were officially

welcomed by the Belgian Minister of Education. Sir Eric Maclagan, director of the Victoria and Albert Museum, then gave his presidential address on "The Future of Museums". The increasing tendency in Great Britain for private collections to become absorbed into the public museums of the country, and the continued growth of the latter, has created, he said, a very serious problem, since ultimately the limit is reached beyond which expansion is practically impossible. Those in charge of museums must therefore become more and more selective in the choice of material. The principle whereby the contents of a museum are divided into public collections, exhibited with great care, and study collections available to students, is an ideal one, but it is practically impossible to adapt existing buildings to such a purpose. Another method of limitation, which could be applied to smaller museums, is that of specialisation, whereby individual museums would carry some groups of exhibits as near completion as possible. Museum federations offer opportunities to promote this by means of exchanges.

Above all, Sir Eric said, those in charge of museums should look forward and regulate their own activities with a view to those of their successors. If anything is to emerge unscathed from our troubled times, museums have a higher 'survival value' than almost any other contemporary institution.

The address was followed by a paper from Prof. Jean Capart, *conservateur en chef* of the Musées Royaux d'Art et d'Histoire, on "The Museum Spirit", which is, he said, to restore the voice to the dead. The scientific aspect of museum work is only a beginning; truth must not remain the personal benefit of the scholar, but must be widely distributed.

In the afternoon there were organised tours of the various departments of the Royal Museums of Art and History in Brussels, where in the evening a reception was held.

On the following day, Prof. F. Demanet, of the Musée Royal d'Histoire Naturelle, opened a discussion on "What is the best way of forming a palæontological collection?" The answer is, he believes, by means of regional investigations carried out by specialists, who would note every fact throwing light on the stratigraphy, palæobiology and ecology of the specimens collected. The collection of specimens should, in fact, become a science of observation. After this subject had been discussed by Drs. D. A. Allan and J. W. Jackson, of the Liverpool and Manchester Museums respectively, Dr. W. T. Calman, of the British Museum (Natural History), gave an illuminating account of the planning of the new Whale Room at that Museum, and Mr. K. de B. Codrington rounded off the morning by a scholarly and witty paper on "The Making of Museums".

The afternoon was kept free for visits to the Museums of Fine Arts and of Natural History (the latter remarkable for its fossil vertebrates), and in the evening members were the guests of Burgomaster Max at the Hôtel de Ville.

On Wednesday, July 3, the Museums Association was privileged to attend the centenary celebrations of the Musées Royaux d'Art et d'Histoire, at which Their Majesties the King and Queen of the Belgians were present. After lunch, a visit to the Congo Museum at Tervueren showed how admirably a single Museum could cover all aspects of the Belgian Congo—its history, natural history, economic resources, ethnography and art—and also provided an enjoyable excursion through the Forêt des Soignes. The annual dinner was held in the evening.

The meetings on Thursday, July 4, took place at the International Exhibition at Brussels. After Mr. P. Dikaios had given an account of the reorganisation of the archæological museum at Nicosia, Cyprus, and Dr. H. J. Plenderleith, of the British Museum, had discussed the application of scientific research to the study of works of art—in which he pointed out that the scientific specialist needs a knowledge of painting if he would avoid errors when working in this field—visits were paid to the magnificent collection of "Art Ancien" and to the other attractions, scientific, artistic and popular, of the Brussels Exhibition.

Friday and Saturday mornings were devoted to excursions to Antwerp, with its unique Museum of Printing, the Musée Plantin-Moretus, and to Bruges, where the effective design of the new municipal museum was greatly admired.

During the Conference, meetings were very well attended, in spite of the many counter-attractions of Brussels, of its museums, and of the Exhibition, and at the end of the week those who took part returned to England agreed that the decision to meet abroad had been fully justified by the success of the meeting.

The next annual conference of the Association will be held at the Leeds City Museum and Art Gallery, in July, 1936.

Educational Topics and Events

BELFAST.—At the graduation ceremony on July 10, honorary degrees were conferred upon, among others, Prof. T. G. Moorhead, regius professor of physic, Trinity College, Dublin; Dr. T. Carnwath, senior medical officer, Ministry of Health; Major-General W. P. Macarthur, Deputy Director-General, Army Medical Services; and the degree of D.Sc. was conferred on J. B. Parke for work on the viscosity of emulsions.

DUBLIN.—On July 5 the University of Dublin conferred the following honorary degrees: D.Sc.—Prof. G. T. Morgan, director of the Chemical Research Laboratory at Teddington. Litt.D.—Sir Frederic Kenyon, formerly director of the British Museum. M.D.—Prof. T. H. Milroy, professor of physiology in Queen's University, Belfast, and Sir Norman Walker, direct representative for Scotland on the General Medical Council.

LIVERPOOL.—At a meeting of the Council on July 9, Mr. Thomas Bertrand Abell, professor of naval architecture and dean of the Faculty of Engineering, was appointed pro-vice-chancellor of the University for the session 1935–36. Prof. Abell, who has occupied the chair of naval architecture since 1914, had a distinguished career at the Royal Naval College, Devonport, and has held various appointments under the Admiralty, at the Royal Naval College, Greenwich, and the Royal Naval War College, Portsmouth. During the War he was assistant director of designs to the Admiralty and Ministry of Shipping and was awarded the O.B.E. for his War services.

The Council has also appointed Mr. J. F. Craig to the William Prescott chair of the care of animals as from October next. Mr. Craig has been on the staff of the Veterinary College of Ireland since 1903, having succeeded to the position of principal in 1918.

He has been president of the Royal College of Veterinary Surgeons and is now president of the National Veterinary Medical Association of Great Britain and Ireland. Mr. Craig has been responsible for important researches into diseases of animals in the Irish Free State and has contributed extensively to scientific literature.

SHEFFIELD.—The following appointments have been made: Mr. J. MacD. Croll, to be lecturer in bacteriology; Mr. Mansergh Shaw, to be assistant lecturer in mechanical engineering; Dr. Edward S. Duthie, to be a demonstrator in pathology.

To universities, and the causes they stand for, the series of special university supplements now in course of publication by *Time and Tide* are doing a really valuable service. The third of the series, published with the issue of April 27 under the heading "More and More of Less and Less", elucidates a number of problems, all of first-rate importance, associated with the growth of specialisation in universities. Mr. R. H. S. Crossman's article on "The Problem in Philosophy" sketches with firm lines the situation confronting the modern student of philosophy. Lacking a comprehensive grasp, such as he cannot hope to compass, of the structure of modern scientific thinking, he tends to subside into the rut of history of philosophy on traditional lines or to give himself up to the exploration of the mazes of logistics. A better way is, however, open to him, pending the discovery of means whereby he may be equipped for holding converse with mathematical and physical scientific workers on their own ground: the study of politics and ethics, not *in vacuo* but in relation to contemporary issues. Mr. C. M. Bowra, discussing science and the humanities as studied in the older universities, suggests, *inter alia*, the institution of a course analogous to Oxford's "Modern Greats" combining with philosophy, physics or biology or chemistry. Three other articles deal mainly with conditions of study, in some respects deplorable, in the modern English universities: by Prof. E. R. Dodds on "Departmentalism and Humane Culture", Mr. Pilley on "The Universities and Science" and Mr. Mansell Jones on "'Facts and Skills' or Education". Lastly comes a study of the situation at Durham. A brief retrospect of the salient features of the history of this university is made to illustrate causes and effects of specialisation, and the recent Royal Commission's recommendations are used to point a moral and adorn a tale.

Science News a Century Ago

Progress of Colonel Chesney's Expedition

IN his expedition to the Euphrates in connexion with the project of shortening the passage to India by means of steam navigation, Colonel Chesney had met with some opposition from the Pasha of Egypt, who, however, had given way, and in a letter from "Port William" on the upper Euphrates, dated July 21, 1835, Chesney remarked, "We arrived here four days ago, and the spot where we are at work, has been named as above, in honour of our earliest patron, the King. We are making efforts of no common kind to get afloat, so as to reach Bussora in time to sail from thence upwards, about the 30th of September".

"I put up the little steamer at the Orontes as a sort of hint, that we did not mean to be stopped, but his Highness gave way, and instead of making our steamer take the gear up to Antioch, we broke her into eight sections, and placed them on keelsons and other pieces of timber, with wheels underneath to make their way by land. . . ."

"I do not expect to finish the steamer before we sail downwards, but she will probably be decked and in working trim, as a shell, in which we must rough it as is done here where there are a couple of habitable rooms, some sheds covered with branches, and tents . . . and the whole enclosed by a parapet and ditch, which were thrown up and just completed by one of the officers. . . ."

The Horticultural Society

ON July 21, 1835, a paper was read to the Horticultural Society, by J. Disney, "On the Preservation of the Golden Harvey Apple," a variety so well known for its excellence and general utility that a really good plan for prolonging the period of its maturity was a desideratum.

It was announced that the annual gold medal about to be given by Lord Grey of Groby, for the finest orchideous plants exhibited, had been adjudged to Mr. James Bruce, gardener to Boyd Miller, Esq., of Mitcham, for an extremely fine plant of *Oncidium ciliatum* with forty-four flowers in its panicle which was shown at the meeting on November 4, 1834 (*Athenæum*).

Lyell and the Continental Geologists

WRITING from Paris to Sedgwick on July 23, 1835, Lyell said: "I found here Von Buch, E. de Beaumont, Dufresnoy, Constant Prévost, Virlet, Boué, Alex Brogniart, and have had much talk with all of them, and some warm discussions with Von Buch and de Beaumont. Of the first, I must say that I found much to like in him. As I had handled some of his opinions very roughly, and as he is too much accustomed perhaps to have unbounded deference paid to him by most of his own countrymen, and by no one more so than E. de Beaumont, I had no right to expect a very cordial reception, but he met me with great frankness, and at once set me at ease by vehemently protesting against my numerous and crying heresies, none of which, not even the elevation crater theory, seems to have exacted so much honest indignation as my recent attempt to convey some of the huge Scandinavian blocks to their present destination by means of ice. . . ."

James Bowman Lindsay's Electric Light Experiments

THE *Dundee Advertiser* on July 31, 1835, said: "Mr. Lindsay, a teacher in town, formerly lecturer to the Watt Institute, succeeded on the evening of Saturday, July 25, in obtaining a constant electric light. It is upwards of two years since he turned his attention to this subject, but much of that time has been devoted to other avocations. The light in beauty, surpasses all others, has no smell, emits no smoke, is incapable of explosion, and not requiring air for combustion can be kept in sealed glass jars. It ignites without the aid of a taper, and seems peculiarly calculated for flax houses, spinning mills, and other places containing combustible materials. It can be sent to any convenient distance, and the apparatus for producing it can be contained in a common chest".

Societies and Academies

PARIS

Academy of Sciences, June 3 (*C.R.*, 200, 1893–1996). LUCIEN CAYEUX: The constitution of the Senonian phosphates of Palestine and Transjordan. LOUIS JOUBIN: The plankton cephalopods of the Atlantic Ocean (cruises of the *Dana* in 1921–22). ANTONIN GOSSET and IVAN BERTRAND: The utilisation of a segment of marrow as a heteroplastic graft of the peripheral nerves. SERGE BERNSTEIN: Some extremal properties of successive integrals. EMILE MATHIAS: The curvature of the diameter of the densities. JEAN CABANNES: The red lines of oxygen in the nocturnal sky. RENÉ MAIRE and ERNEST WILCZEK: The vegetation of the western Sahara. HUSNI HAMID: Regular varieties of higher order. SIMON DE BACKER: A new form of the equations of the dynamics of gases. GEORGES DURAND: The exactness of Eddington's mass-luminosity relation. CHARLES BORY: The natural convection of wires: the existence of a new state of convection. With a very fine wire (25 microns), measurements of the convection coefficient indicated the existence of two regimes. PIERRE VERNOTTE: The laws of convection. Theoretical discussion of the experimental results in the preceding communication. JEAN VILLEY: The calculation of the energy loss on combustion. LÉON DUBAR: The influence of vapours and occluded gases on the electrical conductivity of cuprous oxide. The electrical conductivity of compact cuprous oxide is reduced by water vapour. JEAN GENARD: The action of the magnetic field on the absorption bands of the molecules of sulphur. FRED VLÈS and ERWIN HEINTZ: The infra-red spectrum of protein substances. HENRI MURAOUR and GABRIEL AUNIS: The agreement between the calculated and experimental pressures for explosive mixtures giving rise to gases rich in steam. MARCEL LECOIN: The β-radiation of actinium *C″*, of mesathorium 2 and of uranium X_1 and its derivatives. MME. LUCILE S. MATHIEU-LÉVY: The spectrophotometric study of the adsorption of copper in ammoniacal solutions by precipitated ferric hydroxide. WILFRIED HELLER: The determination of atmospheric ozone by fluorescein. This has advantages over the iodometric method; but may give high values owing to the presence of oxides of nitrogen in the atmosphere. EMILE ELCHARDUS and PAUL LAFFITTE: The constitution of the magnesium-zinc-silicon alloys rich in magnesium. MME. LÉONE WALTER LÉVY: The basic magnesium carbonates. MME. ZINA SOUBAREW-CHATELAIN: Mannitodimolybdic acid. The complex acid, the existence of which had been deduced from physical measurements by Honnelaître, has been isolated and has the constitution $H_2Mo_2O_7,C_6H_{14}O_6,H_2O$. GEORGES RICHARD: Contribution to the study of the α-halogen ketones. HENRI LONGCHAMBON and GEORGES MIGEON: The definition of the sepiolites. STOYAN PAVLOVITCH: Study of the Zlatibor gabbros (western Serbia). RENÉ PERRIN: Metamorphism generator of folds. JEAN LOMBARD: The geological structure of central Oubangui-Chari. GABRIEL LUCAS: The age of the Djebel Tenouchfi (Department of Oran) layers. JEAN DRESCH: The recent formations of Haouz de Marrakech. PAUL DELEAU: The facies of the lower Cretaceous of the region of Hammam Meskoutine (Constantine). GEORGES DENIZOT: The tectonic of the Nerthe and the Etoile, near Marseilles. GEORGES CORROY: The bases of the Hercynian massifs of the neighbourhood of Toulon. WILLIAM HENRI SCHOPFER: Generalisation of the auxogen action of the vitamin B_1 on a micro-organism. ROBERT BONNET and RAYMOND JACQUOT: Evolution of the culture media in the growth of *Sterigmatocystis nigra* as a function of the age of the mycelium. RAOUL COMBES: Nitrogen nutrition of the flower. RENÉ SOUÈGES: Embryogeny of the Rosaceæ. Development of the embryo in *Potentilla reptans*. CHARLES CHABROLIN: Germination of the seeds and plant hosts of *Orobanche speciosa*. EMILE MIÈGE: Influence of cold on the conservation and productivity of the potato. Maintenance of the tubers at 4°–5° C. for several months had a favourable effect on all the varieties examined: the state of preservation was perfect and the productivity high. RAOUL LECOQ: In a balanced ration, can the corresponding fatty acids be used instead of glycerides? They cannot. DAVID NACHMANSOHN, JACOB WAJZER and MLLE. RUTH LIPPMANN: The effect of adrenaline on the metabolism of isolated muscle. MME. VERA DANTCHAKOFF: Experimental sexual inversion of the testicular element in the embryo of the fowl. CAULLERY: Remarks on the preceding communication. VICTOR PLOUVIER: Researches on the isomerisation of cyanogenetic heterosides. MICHAEL A. MACHEBŒUF and HENRY CASSAGNE: Chemical studies on the diphtheria bacillus. Fractional extraction of the lipids of the bacillus; separation of the haptene fraction; the presence of soap in the bacillary bodies. ALBERT GORIS and HENRI CANAL: The presence of 2.oxy.5.methoxyacetophenone in the essence of the rhizomes of *Primula acaulis*. FRANCIS RATHERY, LOUIS ROY and MICHEL CONTE: The spontaneous variations of the glycæmic curve of diabetics. JEAN CUILLÉ CHELLE and BERLUREAU: The existence in France of a bovine anaplasmosis of indigenous origin.

LENINGRAD

Academy of Sciences (*C.R.*, 2, No. 2, 1935). M. KRAVTCHUK: An algebraic point in the problem of moments. A. POPOV: (1) On some series. (2) Series containing cylindrical functions. V. KUPRADZE: The problem of unity in the stationary marginal problems of the theory of elasticity. V. ANTONOV-ROMANOVSKIJ: The influence of an unequal distribution of phosphorescence centres and of related factors on the dimming of the Lenard phosphorus. M. KORSUNSKIJ: (1) The curve of mass defect in the heavy elements. (2) Deviations from the Sommerfeld formula for the *k*-levels. A. ZAICEV and G. SPIVAK: On the exchange of energy between atoms of neon, argon and mercury, and a solid wall. N. SELJAKOV and E. SOVZ: The nature of 'recovery' in metals and of the re-crystallisation in monocrystals of aluminium. I. KNUNJANC and M. GERCHUK: The condensation of the α-formyl-succinic ester with esters of α-haloid-substituted acids. I. KITAJGORODSKIJ: Theory of glass manufacture. D. BELJANKIN: Influence of mineralisers on the formation of sinter-corundums. M. CHAJLAKHJAN: The permeability of the plasma in the leaves of spring and winter wheats. M. CHAJLAKHJAN and V. ALEXANDROVSKJA: The nature of photoperiodic after-effect (induction) and on the effect of the length of day on the activity of the oxidising enzymes. M. SHKOLNIK: The need of plants for boron. E. MININA: The influence of the technique of distributing fertilisers on the quality and yield of wheat.

WASHINGTON, D.C.

National Academy of Sciences (*Proc.*, **21**, 181–234, April 15). CARLETON R. BALL: New varieties of Western [American] willows. LINUS PAULING: The oxygen equilibrium of hæmoglobin and its structural interpretation. Assuming that the hæmoglobin molecule contains four equivalent 'hæmes', one equation involving two constants is derived which represents the oxygen equilibrium at constant hydrogen ion concentration, and another similar equation which represents the change of oxygen equilibrium with change of hydrogen ion concentration. These equations give curves agreeing well with experimental curves; they support the view that the four 'hæmes' lie at the corners of a square. B. S. HENRY and A. M. PARTANSKY: The rate and extent of anaerobic decomposition of sulphite waste liquor by bacteria of sea bottom mud. (2) Bacteriological. A number of anaerobic and facultative bacteria were isolated; they seem to be new species. Sulphite waste liquor slows down the growth and fermentation of nine common micro-organisms tried; it is fermented to only a limited extent by these organisms. C. C. TAN: Identification of the salivary gland chromosomes in *Drosophila pseudo-obscura*. CURT STERN: The behaviour of unstable genic loci—a hypothesis. The unstable locus is assumed to be a composite of a gene in its normal locus and its mutant allelomorph laterally attached next to it, the effect being different from that produced when the two genes are located in different chromosomes. J. T. BUCHHOLZ, A. F. BLAKESLEE and A. G. AVERY: Pollen-tube growth of a translocation of the 1·2 chromosome in *Datura*. Translocation was produced by exposure of pollen tubes to radon during their passage through the style. Reduction in rate of growth of pollen tubes from plants carrying the extra chromosomal material appears to occur and is roughly proportional to the amount of extra material present. CHESTER STOCK: Insectivora from the Sespe uppermost Eocene, California. S. LEFSCHETZ: Application of chain-deformations to critical points and extremals. J. W. ALEXANDER: Note on Pontrjagin's topological theorem of duality. SUMNER BYRON MYERS: Connexions between differential geometry and topology. A. G. MARSHAK: The sensitive-volume of the meiotic chromonemata of *Gasteria* as determined by irradiation with X-rays. The inflorescence of *Gasteria* provides a regular sequence of buds, so that the effect of irradiation can be determined at various periods after exposure. The frequency of effects are proportional to dosage of radiation. Using Glocker's equation for the number of photo-electrons traversing a given volume, and measuring the volume of the nucleus and bivalent chromosome of *Gasteria*, the observed frequency of induced abnormalities enables the width of the sensitive portion of the half-chromosome to be estimated and eventually that of the single chromatid. The figures obtained agree well with those obtained from the diameters of simple protein molecules. R. E. BOWEN: Movement of sensory hairs in the ear. The author has previously reported movements of hair in the ear of the catfish. Observations are now recorded of regular movements of the sensory hairs in the ears of two marine teleostian fish, the squirrel fish and the striped grunt.

Forthcoming Events

[*Meetings marked with an asterisk are open to the public.*]

Sunday, July 21

BRITISH MUSEUM (NATURAL HISTORY) at 3 and 4.30.—Mr. M. A. Phillips: "British Mammals".

INTERNATIONAL SOCIETY OF EXPERIMENTAL PHONETICS, July 22–26.—Meeting to be held in London. One joint session to be held with the second International Congress of the Phonetic Sciences.

ELECTRODEPOSITION EXHIBITION, at the Science Museum, South Kensington, July 25–October.
July 25, at 3.—Opening by Lord Melchett.

Culture and Policy in Basutoland

AMONG the simpler peoples, we are told by members of the functional school of anthropological thought, no element of culture can be studied apart from its social context. This axiom, writ large, is the theme of the report of the Commission* appointed by the Secretary of State for Dominion Affairs to inquire into the financial and economic position of Basutoland, of which Sir Alan Pim was chairman and Mr. S. Milligan, representative in South Africa of the Cotton Growing Corporation, and Mr. H. Lesley Smith were the members (see NATURE, June 22, p. 1028). Throughout the report, it is evident that the members of the Commission were deeply impressed by the interlock of social and cultural conditions with those of the financial and economic position, present and future, and by the complete dependence of the political and social advancement of the community as a whole on a harmonious adjustment between such of them as will tend to conflict when faced with change; and in effect, as their final analysis of the situation, the conclusion is stressed that failure to guide the cultural and ethnic characteristics of the Basuto nation into a path which will open the way for a progressive policy, will lead to complete political and cultural breakdown. Basuto society, as at present organised, according to the Commission, is unable to adjust itself to meet the economic strain.

It is a remarkable symptom of the sensitiveness of the modern world as a whole to the influences affecting any one of its parts in any serious degree, that the economic depression which has crippled the more advanced civilisations has not passed by the backward peoples. Over-production and unemployment find their counterpart in the relatively more primitive communities, though not always recognisable as such when translated into terms of non-European culture. Among the pastoral and semi-pastoral Bantu peoples of Africa, especially in the south of the continent, overstocking of the pastoral lands, made possible by the extra-territorial employment of labour, takes the place of the over-production and maldistribution of commodities, while the social consequences of unemployment find their parallel in the effects of the shortage of cultivable land, which bars an appreciable number of the members of the tribe from full participation in the organisation of the community, owing to the lack of the 'lands', which a man is eligible to hold for cultivation on marriage as an essential concomitant of family life.

It is to be noted, however, that the depression is not entirely responsible for this state of affairs. Rather, it has aggravated a situation which has grown out of certain characteristics of Bantu culture. These tend to give rise to difficulties, which become acute when brought into touch with modern economic conditions, especially the employment of native labour at a remuneration, and the introduction of an effective system of administration, eliminating such checks on over-population and its consequences as warfare and freedom of movement, which mitigated these evils under the old tribal regime.

In all three of the South African Protectorates, the financial and economic outlook is grave. Basutoland, though by no means in such serious straits as Bechuanaland, has almost entirely dissipated its financial reserves, accumulated in a period of prosperity, through the measures of

* Financial and Economic Position of Basutoland: Report of the Commission appointed by the Secretary of State for Dominion Affairs, January, 1935. Pp. viii+225. (London: H.M. Stationery Office, 1935.) 3s. 6d. net.

relief which have been necessitated by the fall in the value of its exports of wool, which now stands at less than a third of what it was a few years ago and will fall still lower, and the effects of a two years' drought. The seriousness of the crisis may be gauged by the fact that not only the holdings of sheep, but also the stocks of cattle, the most essential possession of Bantu culture, have shrunk to one half in this time of distress. This catastrophe, however, is by no means an unmitigated misfortune. It has, to some extent, though not entirely, automatically relieved the over-stocking of the pasture land. A further relief has come with the rains. But neither the rapid recovery of vegetation, notwithstanding the onslaughts of the locust, nor the nearer adjustment of stock to the carrying capacity of the land—possibly temporary and pending the return to individual prosperity—will afford any substantial help towards the solution of the problems of Basutoland's future economic and financial stability. The causes are more deeply rooted.

Basutoland, which is one of the most pleasant, is also in part one of the most thickly populated areas of South Africa. Occupation is, or was, confined almost exclusively to the lowlands, which in the semi-pastoral, semi-agricultural economy of the Basuto are mostly under cultivation. The hill regions are devoted to seasonal grazing. In recent years, however, scattered villages have begun to appear in the uplands, though owing to the consequent reduction of pasture and other evils, these settlements have been forbidden by the Paramount Chief. This veto to a certain extent has been ignored.

In a little less than forty years, the population of Basutoland has more than doubled. It is now estimated to stand at 570,000. This is not entirely a natural increase. There has been a considerable immigration of Tembus from the Union, their accession increasing the prestige of the chief. The Basuto, like a number of other Bantu peoples of South Africa, such as the Matabele, came into independent existence during the troubled times of the beginning of the nineteenth century. Unlike others, however, they were not a single tribe or a homogeneous group, but a congeries of unrelated groups, who gradually came to form a confederation under the Bakwena, or "People of the Crocodile", and were moulded into a nation under the prolonged rule of Moshesh (*reg.* 1815–70). Further, throughout their relations with the whites, they were never subdued, but maintained their independence. These are crucial facts in determining the character of present problems and the method to be adopted in the approach to their solution. The dominance of the Bakwena has by now, for the most part, eliminated the original tribal chiefs, and through the system of 'planting out' the younger sons of chiefs as subordinate chiefs, each with a court, a chief's holding of land, and a revenue dependent on fines, has produced a complicated and ever-increasing system of chiefs and jurisdictions of which the possibilities of abuse are obvious, especially as these petty chiefs have acquired a taste for the luxuries of modern civilisation, such as the motor-car, which their legitimate financial resources scarcely permit them to gratify. One serious defect of the system is that it has gravely affected the security of land-tenure, as the land, which in theory belongs to the Paramount Chief as trustee for his people and is at his disposal, may be required at any time for the settlement of a new chief.

As a result of their past history, both chiefs and people are acutely conscious of their independence, and although the people are by no means satisfied under the multiplicity of chiefs and fully alive to the defects of character and weaknesses of individual chiefs, they are intensely loyal to the chieftainship as an institution. Any change of custom, however advantageous, would meet with serious resistance, if it were held to be an encroachment on their independence or the prerogative of the chief.

Such interference is clearly foreshadowed in the far-reaching recommendations of the Commission. Although administration as such does not come within its province, the members have accepted the position that custom, social organisation and financial and economic stability are so closely interrelated, that if the reforms which they consider essential are to be carried out with financial assistance from outside, administrative changes and cultural modifications are essential which will necessitate a drastic change in what has hitherto been a policy of non-interference in internal affairs—of protection without control.

The three elements in Basuto culture, which thus insistently demand attention—the position and authority of the chief, the holdings of stock and the system of land tenure—are everywhere among the Bantu crucial problems of administration. In Basutoland these elements in culture, operating without check in certain directions, have reinforced the natural tendency of the

country to surface erosion and thereby added to the difficulty of the social and economic situation. This applies more particularly to overstocking and the consequent overgrazing, and to the breaking up of the upland pastures for cultivation, owing to the shortage of 'lands' in the lowlands. The removal of the natural protection of the surface soil by these agencies destroys fertility and leaves the land a prey to weeds. The evil is progressive; and the elements in culture which have aggravated the trouble are, as indicated, equally an obstruction in the way of remedial measures. Even if the country had the requisite financial resources, the essential reorganisation for reform of practice is beyond the competence of existing authority. The policy of non-interference is plainly no longer in the interest of the Basuto nation or its future as an integral part of South Africa.

Of possible alternatives, the Commission favours the introduction of a real and effective system of 'indirect rule', operating through a reformed chieftainship and based upon the intense loyalty of the people to the institution of the chieftainship. Only thus, the Commission holds, will it be possible to put into operation measures to check progressive deterioration in the economy of the Basuto and set them on the way to a return to the prosperity which they enjoyed up to a few years ago.

The report of the Commission is neither concerned with nor mentions the question of the future of the Protectorate in its specific relation to the Union of South Africa. On this aspect the recently published White Paper (see NATURE, July 20, p. 96) has cleared the air by its insistence on the necessity for a breathing space to allow a policy formulated in the interest of the native to come to fruition. Not only does it reaffirm the obligation of the British Government to consult the native population of Basutoland, as well as of the other Protectorates, before steps are taken to effect their transfer to the Union, but also it invites the co-operation of the Union Government in the next few years in a policy which will convince the native population of "a real and generous desire to improve conditions in the Territories".

Minerals and International Security

The Mineral Sanction as an Aid to International Security

By Sir Thomas H. Holland. Pp. 96. (Edinburgh and London: Oliver and Boyd, 1935.) 2*s*. net.

THIS interesting little book appears at an opportune moment. Books on international affairs are indeed numerous, and we have plenty of books on minerals; but minerals in relation to international security, and a thesis that the war-like disposition of an aggressor nation can be and should be held in check by a sanction based on mineral supplies, is a fairly new theme, a consideration of which serves to show how vitally necessary for war purposes, as well as for industrial purposes, mineral supplies really are. So long ago as 1929, Sir Thomas Holland discussed the suggestion in his presidential address at the meeting of the British Association in South Africa.

Minerals indeed, as the very stuff of the earth, are fundamental substances. Man has long used the metals, but not until the industrial era did he begin to develop their specialised uses for the purposes that fill so important a place in modern industry. The utilisation of iron and steel at the present day involves the use of a number of alloy metals, including manganese, chromium, nickel, cobalt, tungsten, molybdenum and vanadium, without access to which the metallurgy of iron as we now know it would not be practicable. Iron and the ferro-alloy metals are essential as munitions of war. So are aluminium, antimony, copper, lead, quicksilver, tin and zinc, and some of the more important non-metals, including fluorspar, graphite, magnesite, mica, petroleum and sulphur. All these minerals are briefly and simply accounted for in Part 3 of this book, in which a short account is given of their importance as war materials.

In Part 2 an account is given of the mineral position in each of the important industrial countries, including the United States, Great Britain, France, Germany, Italy, Japan and Russia, showing with which of the important minerals and metals these countries are well supplied and those in which they are deficient.

The British Empire is well equipped with minerals as a whole, but constituent countries considered separately are seriously deficient. The United States, considered as a geographical unit, is better provided for than any other country as regards war minerals. France, Germany, Italy and Japan each has a long list of war minerals

for supplies of which it is dependent on imports. Russia has large but imperfectly developed resources; and although it is somewhat uncertain how she stands as regards home supplies of many important minerals at present, she has undoubtedly large potentialities.

In an introduction Sir Thomas Holland states his thesis, and in Part 1 he gives an account of the origin and nature of the scheme for mineral sanctions for war conditions. Briefly, the position is that Article XVI of the League of Nations Covenant has proved unworkable. It is therefore suggested that an agreement among the nations to refuse supplies of war minerals to an aggressor would provide a suitable and practicable means of restraining any industrialised power that might wish to resort to war, as war could not be carried on for long without such supplies, and no country is self-contained in this respect.

Sir Thomas claims for this mineral sanction that it can be put into operation immediately, and that it will be so effective that no refractory nation will run the risk of losing by war what might be obtained without, if its cause be just, in the International Court of Justice.

Such is the mineral sanction, about which no doubt much argument is possible. The pressing fact before the world to-day, however, is that war is very much in the air and aggressors are on the move. Whether there be any justification for this aggressiveness leaves unaltered the fact that the world cannot be made safe for civilisation and ordered development unless the policy of settling international disputes by resorting to war be abandoned. There lies, therefore, upon the Governments of the world and on the League of Nations, the big responsibility of exploring fully the possibilities of any suggestions that may be made to secure the desired object of seeking a safe basis for world progress, and for that reason no doubt every attention will be given to the consideration of this mineral sanction in order to ascertain its possibilities as a scheme for preventing wars. Certain it is that the days of cheap mineral supplies, as we have hitherto known them, are numbered; and unless Governments plan hard and co-operatively to secure safe conditions for the world's development, without the hindrances and waste that war involves, industrial civilisation as we know it will go to pieces.

As a clearly and simply written account of the bearing of mineral supplies on the problem of international security, this book deserves to be widely read.

Equivalence of the Sexes

Man and Woman:
a Study of Secondary and Tertiary Sexual Characters. By Havelock Ellis. Eighth edition, revised. Pp. vii+469. (London: William Heinemann (Medical Books), Ltd., 1934.) 10*s.* 6*d.* net.

MR. ELLIS suggests in his preface that this book, first published in 1894, may be thought by some to have no longer a useful purpose to serve, as it is supporting a conception towards which general opinion has been moving, that of "the entire equivalence of the sexes". The movement has not, however, been sufficiently rapid to make anything but desirable the preparation of this new and considerably modified edition, with its impartial and critical survey of observations made in many different parts of the world. These have confirmed the author's original view that "the sexes are perfectly poised in complete equivalence".

Sex, it is now generally held, is settled at the moment of fertilisation. With its determination comes not only a development of the gonad-containing organs and of the external structures connected with their functions, but also an interaction of the various endocrine glands which give rise to the distinctive secondary and tertiary sexual characters.

In some directions undoubted differences in these qualities can be established, but even when they are, it is not easy to arrive at the significance of the facts. Readers who look for evidence as to the superiority or inferiority of one of the sexes over the other may not appreciate this book, as very little support is given to either view. In fact, the fallacies inherent in many arguments that have sustained the extremist partisans are clearly and sometimes amusingly exposed.

In the chapter on the head it is shown that many familiar arguments have to give way before a closer and more critical investigation of the evidence. An entertaining illustration of the fitting of fact to theory is met with in the varying statements as to the relative proportions of the frontal and parietal lobes in the female brain. When the frontal lobes were regarded as the seat of the higher mental qualities, evidence accumulated to show that in the female brain the frontal

lobes were small and the parietal large. When further observation gave the parietal lobes pride of place, corrections were soon forthcoming to show that it was the parietal lobes that were smaller. The female brain is certainly on the average absolutely smaller than the male brain, but proportionately to the general body weight it appears to be relatively larger. As for the differences in shape and size of the skull, the author's final summing up is that "It is open to a man in a Pharisaic mood to thank God that his cranial type is far removed from the infantile. It is equally open to a woman to be thankful that her cranial type does not approach the senile."

The difference in muscular strength, now more or less accurately measured as being in the proportion of three to two as between men and women, seems to have been the basis of wages paid to men and women long ago. Records from Suffolk in 1682 give the wages for haymakers as 5*d*. and 3*d*. a day (with meat and drink) for men and women respectively, though for piece work the pay received was generally the same, so that there was no attempt to underpay women as women.

'Affectability', or the quality of responding readily to psychic or physical stimuli, is said to be more highly developed in women than in men, hence also irritability. The neuro-muscular form of this is, Mr. Ellis thinks, relieved by muscular activities such as dancing. Perhaps in this is seen the reason for the liking many women have for knitting or other forms of handwork. Comparisons of the relative delicacy of the senses give some unexpected results, and consideration of the intellectual and industrial aptitudes also leads to interesting and somewhat unusual conclusions.

There is a wealth of material in this book, so impartially presented that very rarely can a different interpretation of the facts available be suggested. The wisdom, the ripe experience and the humanity of the author are shown throughout the book, which should be widely read. He will carry most of his readers with him in the conclusion that "a cosmic conservatism does not necessarily involve a social conservatism". With regard to changes taking place to-day in the relation of the sexes he says: "An exaggerated anxiety lest natural law be overthrown is misplaced. The world is not so insecurely poised. We may preserve an attitude of entire equanimity in the face of social readjustment." If his scientific attitude of mind towards social conditions could be made to prevail widely, there would be less anxiety and more equity in social life to-day, and the world would be a saner and more tolerant place in which to live.

Physics in Chemistry

Hand- und Jahrbuch der chemischen Physik
Herausgegeben von A. Eucken und K. L. Wolf.
Band 1, Abschnitt 1: Theorien des Aufbaues der Materie. 1: Die Grundlagen der Quantentheorie. Von H. A. Kramers. Pp. 222. 18 gold marks.
Band 6, Abschnitt 2: Elektrische Leitfähigkeit. A: Gase, von W. Hanle; B: Flüssigkeiten und Lösungen, von H. Ulich; C: Nichtmetallische Kristalle, von W. Flechsig. Pp. xii+342+18. 32 gold marks.
Band 6, Abschnitt 3: Positive Korpuskularstrahlen. A: Verhalten von Alpha-Strahlen bein Durchgang durch Materie, von H. Pose; B: Kanalstrahlen und ihre Wechselwirkung mit Materie (einschliesslich Massenspektroskopie), von R. Wierl. Pp. 284+10. 40 gold marks.
Band 9: Die Spektren Entstehung und Zusammenhang mit der Struktur der Materie. Abschnitt 1: Atomspektren. Von H. Kuhn. Pp. vi+266. 26 gold marks. (Leipzig: Akademische Verlagsgesellschaft m.b.H., 1934.)

THE enormous advances in physics and chemistry in the last few years have rendered it imperative that reliable and readable descriptions of particular aspects of these branches of science should be readily accessible. Consequently, there have recently appeared many treatises on special branches and one or two monumental handbooks dealing with the whole of experimental and theoretical physics. Few of these works, however, attempt to set forth the results of modern physics with what may be termed a chemical bias.

The new "Hand- und Jahrbuch der chemischen Physik", edited by Eucken and Wolf, is an attempt to present the material in a way which makes it appeal more directly to chemists. However, the complete series of important contributions to the literature of physics and physical chemistry which will soon be available, and of which some portions are now under review, will appeal to physicists who wish to study much that is already familiar to them from another point of view.

The first volume, on the theories of the structure of matter, is opened by a very full discussion of the fundamental bases of the quantum theory, contributed by Kramers. Although this rigorous introduction is provided for readers more immediately

concerned with the mathematical aspects of the subject, it must not be assumed that no provision is made for the reader whose mathematical equipment is limited, and a short but fairly complete exposition of the main conceptions and methods of the new quantum theory is provided in Kuhn's book on atomic spectra. Incidentally, the latter also contains a concise introduction to experimental spectroscopy, a very lucid account of spectra and of individual lines, and an unusually clear account of X-ray spectra.

The section by Pose on the passage of α-rays through matter is excellently illustrated, and gives a comprehensive survey of the subject. It will appeal to many who are well acquainted with the excellent English treatises on radioactivity, for it contains much Continental work which is known in England only to the specialist, and the results of experiment are compared with the predictions of modern theory in a very delightful manner.

Hanle's discussion of electrical discharges in gases is remarkable for the way in which the phenomena of the self-maintained discharge are dissected and described, and the inclusion of an extensive treatment of all the problems of ionisation processes in gases. It would seem, however, that the description of experimental determinations of ionic mobilities has been unduly curtailed.

Ulich's section on the conduction of electricity by liquids will be found most helpful by those who wish to learn as quickly as possible the nature of recent developments, for it contains much information which is not readily accessible elsewhere, and at the end of his section he gives a summary of results and indicates the paragraphs where particular pieces of information may be found. Considerable attention is devoted to solvation numbers, and the results of five different methods of measuring hydration numbers are discussed. Flechsig's section on the conduction of electricity by non-metallic crystals is equally interesting.

All the books under notice clearly indicate how important an addition to the literature of science the new venture is likely to prove.

The Foundations of Mathematics

Grundlagen der Mathematik

Band I. Von D. Hilbert und P. Bernays. (Die Grundlehren der mathematischen Wissenschaften in Einzeldarstellungen mit besonderer Berücksichtigung der Anwendungsgebiete, herausgegeben von R. Courant, Band 40.) Pp. xii + 471. (Berlin: Julius Springer, 1934.) 37.80 gold marks.

THAT the foundations of mathematics are important is a proposition which will find few opponents, for the science of mathematics is commonly regarded as man's securest intellectual possession. What constitutes these foundations is a subject on which agreement has not been reached. There are, however, three main directions into which the body of modern research has branched, namely, the logistic, the intuitionistic and the formalistic theories. Broadly speaking, the logistic theory regards mathematics as a branch of logic, the intuitionistic theory regards the theorems of mathematics as having actual significance, the formalistic theory regards mathematics as devoid of meaning *per se*. The most powerful exponent of the formalistic attitude is Hilbert, and the present volume is the first part of a systematic exposition of mathematical foundations from the point of view of the school of thought which he has founded. This is probably the most important book on mathematical foundations which has appeared since Whitehead and Russell's "Principia Mathematica".

Hilbert gives the name *Beweistheorie* or 'theory of demonstrations' to his method. The term 'Metamathematics' is also used. The fundamental ideas of the *Beweistheorie* are the following.

(1) The subject matter of mathematics consists of concrete symbols (*Zeichen*) which are immediately recognisable, in fact, the marks on paper which the mathematician habitually uses.

(2) The theorems of mathematics are replaced by formulæ by means of the logical symbols

$$\rightarrow \quad , \quad \& \quad , \quad \vee \quad , \quad - \quad , \quad (x) \, , \quad (Ex)$$

(implies) (and) (or) (not) (all) (some).

(3) Certain formulæ are set up as axioms.

(4) A demonstration is a 'figure' consisting of inferences made by means of the inference scheme

$$\frac{\mathfrak{S} \qquad \mathfrak{S} \rightarrow \mathfrak{T}}{\mathfrak{T}}$$

where each of the premisses $\mathfrak{S}$, $\mathfrak{S} \rightarrow \mathfrak{T}$, must arise (if necessary by substitution) from an axiom or the end-formula of a demonstration.

Axioms and end-formulæ of demonstrations are called 'demonstrable formulæ'.

The procedure just outlined leads to a purely formal mathematics, which contains formal rules of demonstration but is incapable of making significant logical inferences. In particular, that a formula which has the form of a contradiction cannot arise among demonstrable formulæ is incapable of formal proof since formal mathematics does not contain such a significant proposition. That a system of axioms should not lead to contradiction is, however, an essential point, and it is here that the essence of the *Beweistheorie* lies. Hilbert therefore adjoins :

(5) Parallel to mathematics we have meta-mathematics, which allows significant judgments on mathematics. Such judgments must be intuitive (*anschaulich*), directly evident inferences such as $1 = 1$.

The application of this principle to the proof that a given system of axioms cannot lead to contradiction is as follows. Let P denote the property that each demonstrable formula has *not* the form

$$\mathfrak{A} \ \& \ \overline{\mathfrak{A}}.$$

It must first be proved in full finite detail that each axiom has the property P. It must then be proved that the application of the rules of inference (4) does not destroy the property P. This proof must also be so devised that it can be carried out in full finite detail in every particular case. Assuming that this can be done, it follows that the given system of axioms cannot lead to contradiction. This is, in fact, equivalent to the proof that $1 \neq 1$ cannot be the end-formula of a demonstration. For certain systems of axioms the proof is completely carried out in this volume. Hilbert is convinced that it will ultimately be possible to carry out the proof for a set of axioms on which the whole of analysis can firmly rest.

It cannot be denied that the *Beweistheorie* has serious critics. In fact the publication of the first volume was delayed, and a second volume was required, on account of certain results of Gödel which seemed to point to the impossibility of carrying out the full programme. Another serious difficulty is the meaning of words, which necessitated the recasting of the chapter on the *Aussagenkalkul* to avoid an interpretation put by Scholz on this subject in Hilbert and Ackermann's "Grundzüge der theoretischen Logik", an interpretation other than that intended by the authors.

Nevertheless, the *Beweistheorie* has cleared the ground in many fundamental problems, has produced sharp formulations of some aspects, and has suggested means of tackling the problems thus raised. Even if one were seriously to entertain the idea that Hilbert has reduced mathematics to a game, it would have to be admitted that the game is certainly not an easy one. Perhaps one quotation may be allowed.

"Die Methoden der Analysis sind in einem Ausmass erprobt, wie wohl sonst kaum eine wissenschaftliche Voraussetzung, und sie haben sich aufs glänzendste bewährt. Wenn wir diese Methoden unter dem Gesichtspunkt der Evidenz kritisieren, so entsteht für uns die Aufgabe, den Grund für ihre Anwendbarkeit aufzuspüren, so wie wir es überall in der Mathematik tun, wo ein erfolgreiches Verfahren auf Grund von Vorstellungen geübt wird, die an Evidenz zu wünschen übriglassen."

L. M. MILNE-THOMSON.

The Electronic Structure and Properties of Matter: an Introductory Study of certain Properties of Matter in the Light of Atomic Numbers. Being Vol. 1 of "A Comprehensive Treatise of Atomic and Molecular Structure". By C. H. Douglas Clark. Pp. xxvi+374. (London : Chapman and Hall, Ltd., 1934.) 21*s.* net.

THIS book, written by a chemist for chemists, sets out to review recent progress in atomic and molecular theory and to correlate various properties of matter such as cohesion in terms of the electronic structure of atoms. The first section is devoted mainly to a description of the quantum numbers of electrons in atoms, the principles underlying the electronic structure of atoms and the characteristic features of the Periodic Table. The quantum numbers used in the old orbit theory are described in some detail and then a brief account is given of the modifications found necessary in the new quantum mechanics.

This historical method of approach has its disadvantages, for it necessitates the description of symbols which are afterwards discarded. The description of modern quantum numbers is brief, and there is little indication of the interpretation which can be given to them, so that the reader will have no option but to memorise the list of symbols given. Once the quantum numbers are dealt with, the author proceeds more happily to the discussion of the electronic structure of the transition elements and the rare earths and the explanation of some of their characteristic properties. In the second section of the book, methods are discussed of determining the sizes of atoms, ions and molecules, electric and magnetic properties of the elements and the various types of cohesive forces.

The treatment is light rather than profound, and is apt to be sketchy, and to convey the impression of a series of abstracts of papers. None the less, the book provides an easy introduction to a subject which is likely to become of increasing interest to chemists and is not easily accessible elsewhere. Doubtless many will be stimulated by this broad survey to pursue the subject further, and they will be helped to do so by the excellent list of references at the end of each chapter, a feature which adds considerably to the value of the book.

Das Giftbuch des Śanāq : eine Literaturgeschichtliche Untersuchung

Von Bettina Strauss. (Quellen und Studien zur Geschichte der Naturwissenschaften und der Medizin, Fortsetzung des Archivs für Geschichte der Mathematik, der Naturwissenschaften und der Technik. Herausgegeben vom Institut für Geschichte der Medizin und der Naturwissenschaften, Band 4, Heft 2.) Pp. 64+66. (Berlin : Julius Springer, 1934.) 15 gold marks.

THIS book contains the Arabic text, with an annotated German translation, of the "Book of Poisons" of Śānāq, that is, Cāṇakya (Chanakya), the minister of King Chandragupta (fourth century B.C.). The Arabic version is not a direct translation of an Indian original, but is rather a compilation from both Indian and Greek sources. It was apparently based on a Persian translation of an Indian "Poison-book of Chanakya" made by an Indian physician, Mankah, of the celebrated hospital at Jundi-Shapur. Mankah also translated other Indian medical books, such as a treatise on the names of drugs, and a medical compendium of Susruta. The Arabic version of the "Poison-book" was made from the Persian by one Abū Ḥātim of Balkh, about whom we have no information. It was later re-edited by Al-'Abbās ibn Sa'īd al-Jauharī, who was probably responsible for the introduction of the Greek material.

The book gives a useful picture of early Muslim pharmacology, in which much shrewd and careful observation was diluted with at least as much matter of an unreliable and fanciful character. The Arabic text has been well established and is clearly printed, while the German translation follows the original with close accuracy. It is, however, a great pity that no index of any kind is provided. E. J. H.

Kleine Meteoritenkunde

Von Prof. Fritz Heide. (Verständliche Wissenschaft, Band 23.) Pp. vi+120. (Berlin : Julius Springer, 1934.) 4.80 gold marks.

THE discussion of meteorites in this handy little volume commences with their entry into our atmosphere ; the cosmogonical interest has to be found by working back from the chemical analysis of their contents. Even the geophysical phenomena relative to the falls of meteors—the information that they have given as to the highest regions of the atmosphere —are omitted from this book, which is strictly limited to the meteorites that fall to earth. Very full details of these, however, are given and much useful information for the geophysical chemist and mineralogist. The introductory historical chapter is extremely interesting. The number of large crater-fields of meteoritic origin will surprise most readers who come newly to the subject, but it is reassuring to find that there is no certain evidence of any person having been killed by a falling meteorite. Photographs of the devastated country in Siberia surrounding the scene of the great fall of July 30, 1908, show what damage can be done and leave one thankful that so far no densely populated country has been visited by a giant meteorite.

Geologie Südamerikas

Von Prof. Dr. H. Gerth. (Geologie der Erde, herausgegeben von E. Krenkel.) Teil 1. Pp. vii+199+17 plates. (Berlin : Gebrüder Borntraeger, 1932.) 22 gold marks.

THIS volume is one of the series of monographs on the regional geology of the earth published under the general editorship of Prof. Krenkel, and deals with the South American continent from the Pre-Cambrian up to the end of the Palæozoic.

The aim of the author has been to provide, not a detailed regional description but a comprehensive general introduction to South American geology and its problems. At the same time the needs of the reader requiring more precise and detailed information on any particular area or subject have not been lost sight of and each section of the book is provided with an extended bibliography.

Approximately half the book is devoted to a consideration of the Pre-Cambrian basement of the continent, and the structural, petrological and tectonic problems are dealt with rather fully. This is by no means excessive in view of the structural importance of the Pre-Cambrian in South America. Each region is considered separately and then the continent as a whole is dealt with in a concluding section. Much the same method of treatment is adopted throughout the remaining chapters on the Palæozoic systems, and the volume concludes with a chapter on the so-called 'Gondwanides'.

The author has brought together a great mass of information from scattered and often inaccessible sources, and has provided a most useful, up-to-date and well illustrated treatise on South American geology.

Dix leçons d'astronomie

Par Ernest Esclangon. Deuxième édition revue et corrigée. Pp. 116+20 plates. (Paris : Gauthier-Villars, 1934.) 25 francs.

IN this volume of popular lectures, the director of the Paris Observatory has given as simple and clear an account of modern astronomy as can be given in one hundred pages. The style is extremely lucid, as is to be expected in a French book, the facts are accurately given and up-to-date, the illustrations are numerous and the whole volume is very pleasantly readable. In addition to the definitely astronomical chapters, there are two which will be read with much sympathy and interest. The opening chapter gives an account of the importance of astronomy in the past in the development of thought and of civilisation ; the final chapter, after dwelling upon the glories of French astronomy in the nineteenth century, emphasises the reasons why France has of late dropped out of a leading position in astronomical research. Modern developments require large instruments, and so far the money has not been forthcoming from Government or private sources to keep France abreast of most other countries. It is to be hoped that Prof. Esclangon's appeal in this volume may fall upon fruitful ground—and if fresh developments in France react favourably upon Great Britain, so much the better.

Fifty Years' Progress in Marine and General Engineering

JUBILEE OF THE NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS

OF the various industrial districts around the coasts of Great Britain, none has a greater variety of industries than that known as the 'North-East Coast'. Here, situated on the banks of the Tyne, the Wear and the Tees are coal-wharves, ship-yards, engine-shops, steel-works and factories by the score. But the outstanding industries are shipbuilding and marine engineering, and ships built or engined at Wallsend, Elswick, Hebburn, Shields, Sunderland or Hartlepool are found all over the world. As compared with the Thames, the Mersey and the Clyde in the early days of steamships, the district occupied a minor position as a shipbuilding centre. About the middle of last century, however, it began to specialise in the building of economical slow cargo ships, and its success in this direction led to developments which perhaps are as remarkable as they were unexpected. In 1850, the depth at low water over the bar at the mouth of the Tyne was only 6 ft. Now the channel of the river is dredged to more than thirty feet, and into the river have been launched such vessels as the *Mauretania* and H.M.S. *Nelson*. To-day, ships of many classes and marine engines of every type are constructed in the district.

In these circumstances, it was but natural that at the jubilee meeting of the North-East Coast Institution of Engineers and Shipbuilders, held at Armstrong College, Newcastle-upon-Tyne, on July 16–19, the principal papers read should have dealt with the progress of ships and their machinery, while the Citizens' Lecture should be "Ships Through the Ages", this being delivered by Sir Westcott Abell.

The three papers dealing with developments in the construction of ships during the past fifty years were on liners, by Mr. J. D. Christie; on cargo ships and tankers, by Mr. J. McGovern; and on coasters, by Mr. F. W. Dugdale. When dealing with the progress of liners, speakers often confine themselves to the vessels of the North Atlantic, where the largest and fastest ships are found. Mr. Christie, however, took a wider view of his subject and sketched the progress in passengers ships not only on the North Atlantic, but also in ships running between Europe and South America, South Africa, India, Japan and Australia, as well as in those crossing the Pacific. The paper is accompanied by seven useful tables dealing with ships on these various routes. As regards technical problems, he said that, judging by published figures, it does not appear that the latest ships are superior in form to the *Mauretania*, in so far as minimum resistance and propulsive efficiency are concerned. The evidence, too, for the various new forms of bow are conflicting. There is no question of the value of the new tensile steels and of the introduction of welding, while the question of watertight subdivision appears to have reached a certain degree of finality. A great desideratum is the lessening of vibration and the reduction of pitching and rolling, but nothing has yet appeared to show that the Sperry anti-rolling gyroscopes in the *Conte de Savoia* have justified the great cost entailed. In no direction does the passenger liner of to-day present a more marked contrast to the ships of 1885 than in the arrangements for the comfort, safety and enjoyment of passengers.

The carriage of coal, grain, ore, timber, oil, sulphuric acid, molasses and such cargoes present different problems to the naval architect, and in his paper entitled "Cargo Ship and Tanker Development", Mr. J. McGovern described the various types of cargo vessels and their main structural features. The ways in which the plating of a ship may be held together and supported by the internal framing are endless. Special designs of ships developed on the North-East Coast have been the 'Turret' vessels of Doxford's, the 'Trunk' vessels built at Stockton and the Priestman 'Self-Trimmer' type built at Sunderland. One of the landmarks in ship construction was the introduction in 1906 by Sir Joseph Isherwood of the longitudinal system, giving increased strength with less weight of steel. To him also is due the recent radical departure from the orthodox box form of section designated the 'Arcform', wherein he has adopted a midship section shape entirely dispensing with the square bilge long familiar. Extensive model experiments and actual voyage performances of three 'Arcform' vessels have proved them to be the most economical cargo-carrying vessels of their class afloat to-day.

It is acknowledged by all that while many improvements in the structural details of ships have been made during the past fifty years, the improvements in machinery have been still more striking. Half a century ago, the majority of vessels were driven by compound engines using steam at comparatively low pres[illegible]

consumption was high, boilers were heavy, marine auxiliaries were unsatisfactory; the water-tube boiler was in its infancy, oil burning at sea was unknown and the marine steam turbine undreamt of except by Parsons. The triple expansion engine, however, was fast making ground, steel was being used for boilers, forced draught was being introduced, engines were getting more powerful and an era of rapid development was setting in. At the jubilee meeting of the North-East Coast Institution four papers on marine engineering touched upon these matters, and briefly described some of the latest innovations. The paper on turbines was by Mr. R. J. Walker, that on reciprocating steam engines by Mr. S. Hunter, Junr., that on boilers by Mr. T. McPherson and that on marine heavy-oil engines by Mr. H. O. Keller. Like the papers on ships, these are all well-illustrated and together constitute a brief but valuable record of achievements to which scores of men of many countries have contributed.

The last paper read, entitled "Recent Developments in Electrical and General Engineering", was by Mr. M. G. S. Swallow. The 'North-East Coast' engineers have a right to be proud of the work done by what to-day is the North-Eastern Electric Supply Co., which Mr. Swallow says "was the prototype of the present interlinked electric supply system of the country". But of more interest than the technical information given in this paper were the stimulating remarks on 'North-East Coast' engineering generally. "The history of our Institution," he said, "is a record of men who have led and achieved in the past. . . . To-day the inventive ability, the scientific knowledge, the tenacity and skill which have made us successful are still ours. Some of our industries may decline temporarily or may be lost to us. But this is no reason for despair or lament. Engineering is not only progressive, but is for ever conquering new fields and our activities spread and continually increase." This undoubtedly is the right outlook for a district which has been rendered famous by the labours of the Stephensons, the Hawthorns, Palmer, Armstrong, Rendel, Morison, Tweedy, Marshall, Noble, Doxford, Laing, Parsons and many other great engineers.

The Economic Importance of the Foraminifera

By Dr. H. Dighton Thomas, Department of Geology, British Museum (Natural History)

PERHAPS the application of science to industry provides no romance equal to that of the smaller Foraminifera. Those earlier research workers, Carpenter, Brady and others, could have had no inkling of the importance that that class of lowly-organised animals was to achieve in the exploitation of oil in various parts of the world. It is the object of this article to explain in outline the way in which the Foraminifera are of use economically.

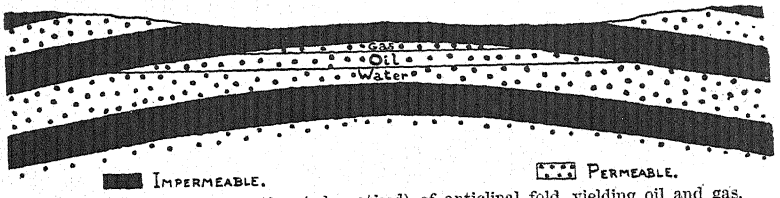

FIG. 1. Diagrammatic section (schematised) of anticlinal fold yielding oil and gas.

The winning of oil from the reservoir rocks (other than those oil-shales which yield it on distillation) depends very largely on the correct identification of the tectonic structure of the petroliferous areas and the exact location of the fold-axes and fault-lines: for in many fields there is a very close relation between the geological structure of the area and the sites of the oil accumulation. Thus, anticlinal folds (Fig. 1) frequently act as the reservoirs, the oil, possibly associated with gas, occurring in a permeable stratum at some depth below the surface, and overlain by impermeable beds which act as a cover. Accurate geological mapping provides the solution of the problem of the tectonic structure, but, as with all such mapping, it is dependent on the correct stratigraphical identification of the rocks.

Although petroleum is yielded by rocks of almost all ages, attention here will be focused on oil-bearing Cretaceous and Tertiary rocks. Many of these beds are often, but not always, rich in small Foraminifera, though other fossils are present also. Although the latter are not neglected by the palæontologists now attached to most oil companies, yet the Foraminifera have received particular attention, both because they often occur in great numbers in small samples of the rocks, for example, shallow auger-borings, and because

of their frequently widespread distribution. It has been shown from this study that in many oil-fields the Foraminifera, properly used, are excellent stratigraphical markers. Naturally, the methods have been applied to the older fossiliferous formations also, but, even where small Foraminifera are relatively abundant, as in some parts of the Carboniferous, opinions are divided as to their usefulness there. But there are no two opinions on the value of the Cretaceous and Tertiary Foraminifera.

In the technical application of the study of this order of the Protozoa, one of the fundamental considerations is that, for a given period, basins of deposition or embayments may be recognised, and that over a large part of each basin the conditions of sedimentation are similar. In the geological history of such a basin (excluding its margins where facies changes, that is, of lithology*, take place) the changes affecting it usually occur contemporaneously all over the basin, so that the stratigraphical sequence is usually constant throughout it, but different from that of neighbouring basins. These have different geological histories and experience different changes, so that each basin has to be studied separately. In addition, where lateral changes of facies occur, due for example to the approach to shore-line conditions, those areas also have to be treated separately.

The foraminiferal fauna of any area of deposition at any given time is related to the conditions then prevailing, so that the changes affecting the area (changes of salinity, depth, temperature, nature of the sea-bottom, etc.) result in changes in that fauna. Thus, in such a basin there is usually found, throughout all but those parts where lateral facies changes occur, a definite sequence of foraminiferal faunas. Some species, although their geological range considered throughout the world is very long, may be restricted to a small thickness, or to one layer in such an area; others may be very common at one horizon, be absent at another, and then reappear (as conditions changed again) either as a common or a rare form.

Thus the relative abundance of a species at a given horizon, as well as its presence, is a point of great importance. In this way, either by the determination of those species which are found to be restricted to definite horizons, or by the faunal assemblages themselves, the Foraminifera have proved in practice to be of great local zonal importance.

This is the more so in those cases where great thicknesses of similar rock types have been laid down over large areas. Thus in some petroliferous regions there are great masses of glauconitic sands and clays, and the determination of horizons and geological structures is not an easy matter without palæontological aid. Moreover, the difficulties are not simplified in those areas where the country is swampy and covered with dense vegetation, so that rock exposures are few. The value of the foraminiferal zones in the unravelling of the geology of these areas is very high, and it is not without importance that the crucial evidence can be obtained from a relatively small amount of the rock.

A standard zonal series for that part of the geological column represented in the area is first established either from a number of natural sections which, when pieced together, give a continuous section, or from artificial sections, such as well-sinkings. A detailed analysis of the foraminiferal fauna of successive levels is made, samples of approximately equal weight being used, so that the relative frequencies of the species may be determined. Permanent records of the species of Foraminifera which have been found, their horizons, and their relative abundance at the various horizons, are then tabulated on charts†, so that the zones can be determined. In this, particular attention is paid to those species which have restricted ranges, to the incoming of species, and to the disappearance of species from the succession (in the latter case, this is equivalent to the incoming of the species in a descending series of samples from a well-sinking). Often the oil palæontologist is not concerned with the scientific names of the species, but instead numbers, or letters and numbers (the combination indicating the locality as well as the species), are allocated to them. Ultimately, however, since inter-regional correlation will become a necessity, the correct scientific identification of the species will have to be made.

After the establishment of this zonal series, its application in the field to the determination of the age of the rock exposures or of core-samples is easily made. In order to facilitate matters, various travelling laboratories have been devised, so that the washing of the clays, and the separating, mounting and identification of the Foraminifera can be made on the spot; or samples—often obtained from shallow auger-borings or small trial diggings—are collected continuously by the field-geologist in a traverse, carefully and accurately labelled, and dispatched as quickly as possible to the palæontologist for investigation. To the field-geologist himself, acquaintance with some distinctive and easily recognisable species is of the greatest use for the preliminary identification of

* As, for example, from limestones to clays and shales.

† See Nuttall, W. L. F., *World Petroleum Congress Preprint No.* 28, 1933.

the stratigraphical horizon of a rock seen in a natural or artificial exposure. From the observations and investigations so made, a geological map can be constructed in the usual way, and the geological structure of the region can thus be determined.

Besides this use in mapping and the location of tectonic lines in an area, the Foraminifera are also useful in connexion with the sinking of wells. In boring to the known oil-bearing stratum, samples of the core are taken at frequent and known depth-intervals, and examined for the Foraminifera, so that a continual check is kept on the depth to which the shaft is to be sunk. Such palæontological observations will also indicate quickly when the productive stratum has been passed (for example, in a fault), or when the well is placed too far from the crest of the oil 'trap' so that it will strike water and not oil (see Fig. 1). The saving in expense by the rapid recognition of the futility of further boring on those sites is obvious.

Further, great wastage of oil has occurred in some fields in the past, because 'gushers' have burst out before it was considered necessary for steps to be taken to prevent this loss. But this has been largely obviated by the sampling of the cores, the Foraminifera giving a sure indication of the horizon reached and therefore of the distance above the oil-bearing stratum. In one field, for example, one species makes its appearance (in the descending series) at a relatively short distance above the reservoir rock, so that its recognition in the core-sample gives the indication that the drill has nearly reached the reservoir rock and that precautions must be taken to prevent loss from the oil 'gushing' on further boring.

It will be seen from the above that the smaller Foraminifera can be used to determine the age of the rocks yielding them, and so, by detailed field collecting and investigation, to unravel the geology of an area. When this has been done, then the knowledge so obtained can be used to determine the best sites for drilling for oil, if oil is present in the area. But there is no causal connexion between the Foraminifera and oil—the presence in an area of a given foraminiferal species, or foraminiferal fauna, or foraminiferal zonal series, is no indication of itself that oil is present, though that, however, is a widely-held misconception.

It is knowledge of the detailed geological structure which is of crucial importance in an area known to be petroliferous. But the Foraminifera, if intensively collected and the results from innumerable rock-samples carefully analysed, often supply the key to the problem of the determination of that structure.

A Postscript upon the "Origin (and Development) of Species"

By Edward Heron-Allen, F.R.S.

In the foregoing article Dr. Dighton Thomas has efficiently dispelled the somewhat widely-spread illusion that Foraminifera, *per se*, especially certain genera and species, indicate the occurrence of mineral oil at a given depth. There are certain ascertained phenomena which indicate the presence of oil in a district, and it is when the 'show' has been observed and noted, that the importance of the Foraminifera to the 'petroleum geologist' becomes apparent. A word of warning to the young geologist, who has now become a necessary official attached to every petroleum company of any importance, should perhaps be added: Let him firmly ignore what Earland has rightly called "the spate of literature" and I have called "the proliferation of nomenclature". The industrious Dr. Hans E. Thalmann has recorded three hundred and eight papers on the Foraminifera published in the years 1931 and 1932, and to these may be added scores of later papers noted in the "Zoological Record" and in the lists periodically published by Dr. Cushman since that date.

What may be called 'the Commercialisation of Protozoology' has, however, had one beneficial effect—a blessing in a deplorable disguise—and that is that there would have been as many papers again published, were it not that the Foraminiferal fauna of a given district have risen—or fallen—to the rank of a trade-secret, and many oil companies jealously guard their zoological records (and even specimens of material from their bores) from the prying eyes of rivals in the trade.

The shattering fact has already been recorded in these pages*, that of recent years the number of genera forced upon protozoology amounts to five hundred and fifty-eight (not counting sub-genera), whilst as regards species the brain simply reels. It is not humanly possible to keep track of them, but anyone who pays any attention to the literature of Foraminifera gradually realises that professional rivalry has something to do with it. Profs. A, B and C are the recognised authorities of as many rival schools of foraminiferal research, which appear to race one another in the recording of new species (and even genera) and each school is ready to swoop, vulture-like, upon the announced discoveries of its rivals, and to pick them to pieces, fondly imagining that students will collect for themselves a new working nomenclature out of the *disjecta membra* left after their attacks upon one another.

I enjoy being 'howled down' by the spokesmen of the advanced schools of petroleum geologists,

* Heron-Allen, NATURE, **134**, 43, July 14, 1934.

and I continue to advise the young men, who recurrently visit our collections at the Natural History Museum, to revert boldly to the bygone nomenclatures (condemned by some) of the great *scientific* Foraminiferists, who died in peaceful ignorance of the pending effects of commerce upon their study—Parker, Jones, Brady, Millett, Williamson in our country; d'Orbigny, Berthelin, Schlumberger, Terquem in France; Haeusler, Karrer, Reuss, Schultze in Germany; Costa, Fornasini, Seguenza in Italy—to mention only the names which spring to the memory at once.

The works of these giants will tell them all they need to know. Let them fix this sound *corpus* of genera in their minds, and distinguish the variations of species by numbers, each for himself, species that they will recognise as their own old friends in every district which they have to examine and report upon.

When their work has been done and borne fruit in the form of adequate remuneration, let them if they like—and are allowed by their board of directors to do so—hand their 'mounts' on to the pupils of Profs. A, B and C, and let them fight it out. *They* need not bother about it any more—taking the Omarian advice of the late Aurelius D. Godley:

"The moving Finger writes; then, having writ,
The Product of your Scholarship and Wit
Deposit in the proper Pigeonhole—
And thank your Stars that there's an End of It."

Obituary

Prof. Hugo de Vries, For.Mem.R.S.

BY the death of Hugo de Vries, on May 20, at the age of eighty-seven years, biology has lost one of its outstanding figures in the history of the last century. He proved himself a master of plant physiology in the period 1870–85 when that science may be said to have had its modern beginnings; but the problems of evolution held his attention from the time when, as an undergraduate at Leyden, he read a German translation of the "Origin of Species". The transition from experimental physiology to evolutionary theory took place with the publication of his "Intracellular Pangenesis" in 1889, but his earlier work no doubt made it easy for him to introduce experimental methods into the investigation of evolutionary problems.

The range of de Vries's early physiological researches may be indicated by series of papers on such topics as the permeability of protoplasm, the movements of climbing plants, contractile roots, the germination and growth of such crop plants as red clover, potatoes and sugar beets, the reactions of *Spirogyra* and *Drosera*. A series of investigations on food plants were done for the Prussian Ministry of Agriculture while a student with Sachs at Würzburg.

In his classical researches on the mechanical causes of cell stretching in plants (1877), de Vries introduced the plasmolytic method, determining the osmotic pressures of cells and developing the conception of isotonic coefficients. In 1884, by comparing the plasmolytic effects of many isosmotic solutions, he was able to show that the osmotic pressure depends on the number of molecules in solution. He also used these methods to determine the molecular weight of raffinose. This work formed the basis for the laws of dissociation in dilute solutions, with which the names of the physical chemists Van 't Hoff and Arrhenius are connected.

The intracellular pangenesis was an important development of Darwin's earlier theory of pangenesis. In it de Vries related theories of heredity and development to the increasing knowledge of cells, and put forward the view which modern work has proved to be correct, that every nucleus of the organism contains a full representation of the hereditary materials. In that work is clearly stated the conclusion that "hereditary qualities are independent units, from the numerous and various groupings of which specific characters originate", and for these units he adopted the term 'pangen'. This anticipation of the modern theory of the gene in all its essentials was a masterly triumph of clear thinking—especially when we remember its date, 1889.

In the same work de Vries criticised the views of Weismann, especially as regards his theory of the idioplasm and his idea that a sorting out of germinal materials takes place in different types of somatic nuclei. The influence of these erroneous views would have been avoided had contemporary zoologists been able to recognise that Weismann's elaborate architecture of the germplasm held less truth than de Vries's simpler but better founded theory. The two authors agreed, however, in denying the inheritance of acquired characters.

In the same year (1889) the publications with what we would now call a genetical bearing were begun, with papers on sterile maize plants and on the inheritance of twisted stems. This was followed during the next decade by a stream of papers on similar subjects. From now onwards, heredity and variation claimed the whole of de Vries's interest, yet the problems were viewed from the first with an experimental background.

The turn of the century marked the well-known triple rediscovery of Mendel's principle of segregation in hybrids, which de Vries had confirmed in several plants before publishing his account in 1900. In the meantime, in searching for mutable plants in accordance with his theoretical views, he had begun so early as 1886 the cultivation of *Œnothera Lamarckiana* and the investigation of its variability. His first paper on *Œnothera* appears to have been in 1895, on the introduction of *Œ. Lamarckiana* into the Low Countries. The "Mutation Theory", first published in 1901–3, and afterwards translated into English, will remain a classic as the earliest example of the pedigree method applied to evolutionary problems, and as a statement of the broad biological distinction between mutations and fluctuations which has gained general acceptance in modern biology. It may safely be said that no work since the "Origin of Species" has had so profound an effect on evolutionary thought. The early years of this century were epoch-making, and progress has gone on with increasing rapidity since de Vries and Bateson led the way with the conception of discontinuity, or better, definiteness in variation.

Œnothera became classical material for the investigation of the more complicated problems of genetics and cytology. No other genus of plants has been subjected to such prolonged and extensive genetical investigations. By 1915 the mutations had been analysed in terms of change in chromosome numbers. The succeeding twenty years has disclosed new conditions in the genus, many species have been recognised as heterozygous, with two complexes yet breeding true owing to balanced lethals and fixed chromosome catenations. While the mass of evidence has necessitated many developments and re-orientations in points of view, yet the general conception of mutation which de Vries founded has remained the basis of genetical work, although views still differ as to the value to be attached to mutations as the raw materials of evolution.

De Vries continued his breeding work with evening primroses until the end. In 1909 was published "Species and Varieties: their Origin by Mutation", as a result of an American lecture tour, and in 1913 "Gruppenweise Artbildung", which is entirely devoted to analytical breeding experiments with *Œnothera*. In 1918–20 six volumes of his collected early papers were published, a seventh volume, of *Œnothera* papers (1915–25), being added in 1927.

De Vries was born in Haarlem on February 16, 1848, the son of a former Prime Minister of Holland. After study in various German universities, he occupied the chair of botany at Amsterdam from about 1878 to 1918, and was not tempted away by flattering offers from Berlin, Columbia and other universities. In Holland his name became a household word and in scientific circles his fame spread throughout the world. When he retired at seventy years of age, he went to live in the village of Lunteren. Here he continued his experiments with evening primroses in a private garden and laboratory attached to his residence. Among the numerous scientific honours conferred upon him was the foreign membership of the Royal Society (1905), the Darwin Medal of the Royal Society (1906), and the gold medal of the Linnean Society (1929).

The genius of Hugo de Vries resulted from the combination of an acute, sagacious and clear-reasoning mind with a power of accurate observation which is rarely equalled. Every biologist would gain from a re-reading of "Intracellular Pangenesis", which was translated into English in 1910. It shows how unerringly his reasoning from the few known facts guided him to views which require extraordinarily little alteration in the light of modern detailed knowledge.

R. RUGGLES GATES.

Miss Ida M. Roper

MISS I. M. ROPER, who died at a nursing home in Bristol on June 8, in her seventieth year, was known widely for her devoted work as a field botanist, and as a contributor of well selected dried specimens to both the British Botanical Exchange Clubs. She had been honorary secretary and librarian of the Bristol Naturalists' Society for nineteen years, and was the only woman to become president (1913–16); also the first woman to serve on the Council of the Bristol and Gloucestershire Archæological Society. Her presidential address on mistletoe showed wide research on the host trees of that parasite; and her second annual address was appropriately entitled "Some Historical Associations of Flowers". Her power of organisation was remarkable. In 1920 she joined the Somersetshire Archæological and Natural History Society, and was also a useful committee member of the Botanical Section.

Miss Roper gave great help to the late J. W. White in the compilation of his excellent "Flora of Bristol", 1912, "not only for field work, but for assistance in literary research and in revision and correction for the press". More remarkable is the fact that for thirteen years she made the collecting and exhibition of local wild plants at the Bristol Museum and Art Gallery a labour of love, both in summer and winter. Her own herbarium of British Phanerogams and ferns, good and beautifully arranged, was recently given to the University of Leeds.

Miss Roper had a particularly good knowledge of British violets. Mosses also interested her, and the British Bryological Society excursions were among the numerous scientific or antiquarian meetings which she enjoyed attending. These included many British Association meetings; hence her cheerful and energetic personality was known to many.

In 1928 Miss Roper rediscovered *Erodium Ballii* in Ireland. Jordan had named it in 1852 from Irish specimens gathered by John Ball, F.R.S. In 1920 she found *Euphorbia platyphyllos* at Keynsham, near Bristol, Ray having noticed it in 1670 as a first record for Britain. Other notes and short articles on British flowering plants appeared in the *Journal of Botany* and in the *Proceedings of the Bristol Naturalists' Society*.

During most of her life, Miss Roper had been interested in monumental effigies, and had visited nearly every church in Gloucestershire and Bristol and many in Somerset to collect information. This culminated in 1930 in the publication of a handsome volume on "Monumental Effigies of Gloucestershire and Bristol". H. S. T.

WE regret to announce the following deaths :

Dr. Arthur Bramley, head of the Department of Pure and Applied Science at Loughborough College, on July 19, aged fifty-six years.

Sir John MacFarland, Chancellor of the University of Melbourne since 1918, a member of the Royal Commission (1899) on Technical Education, Victoria, and of the Government Board (1908) for the Protection of Aborigines, on July 22, aged eighty-four years.

Mr. L. M. Nesbitt, who was awarded the Murchison Grant in 1931 of the Royal Geographical Society for "his difficult journey through the Danakil country of Abyssinia", on July 20, as the result of an aeroplane disaster near the San Bernino Pass, Switzerland.

Sir James Watt, a well-known stock-breeder and forester, formerly chairman of the Forest Tree Growers under the Forestry Commission, on July 1, aged ninety-three years.

News and Views

International Folk Dance Conference

IN another column of this issue of NATURE (see p. 154) there appears a brief account of the conference, which formed part of the International Folk Dance Festival held in London last week. Lack of space for fuller reference does less than justice to a kaleidoscopic spectacle, of which the interest to students of the development of social custom and religious belief, more particularly in Europe, was profound. In its general results, the conference on the scientific aspect of the folk dance has made a very appreciable contribution to the advancement of this branch of the study of the art and life of the 'primitive' element in European populations, both of to-day and in the past. In its effect on future development, it should stimulate the application of that study to the revival and extension of the practice of folk dancing, as well as, possibly, lead to restoration of forgotten or neglected elements where traditional dances and customs are still a living factor in peasant life, as has already happened in certain of the dances which appeared at the festival. On the other hand, the references of many speakers to the obsolescence of traditional customs and dances among the folk and the contrast in the spirit of such dances as those of eastern Europe—for example, the hobby horse dance of the Calušari from Rumania—when the dance is a living functioning element, integral in rural life, argues that the folk dance as a revived art can become a factor in communal life once more only as an attenuated and, to a considerable degree, sophisticated form of expression. Its essential meaning vanishes with the fading away of its economic and magical background.

African Problems

SIR MALCOLM HAILEY, lately Governor of the United Provinces, India, and now director of the African Research Survey, accompanied by Mr. Donald Malcolm, formerly of East Africa, will leave England on August 15 for the purpose of a prolonged journey of investigation on the African continent. During an absence which is expected to extend over a period of eight or nine months, Sir Malcolm Hailey will be engaged in testing and amplifying material which has been collected for a survey of African problems in a report to be published, if possible, in 1937. The survey has been undertaken by a Committee, of which Lord Lothian is chairman, as the result of a suggestion, made by General Smuts in his Rhodes lecture at Oxford in 1929, that it was time to consider how far the resources of modern knowledge were being applied to the problems of Africa, and how far it was possible to co-ordinate the experience of the different territories. The scope of the survey has been limited to Africa south of the Sahara. It will deal with the problems of each territory in the administrative, economic and scientific fields, and will estimate the character and amount of the material available for their study, as well as suggest the lines on which further research and extended study might prove profitable. The aim of the report will be to state facts rather than to criticise methods and results. Dr. E. B. Worthington, of the Department of Zoology, University of Cambridge, has been engaged for some time in digesting the facts relating to research bearing on Africa in all the physical sciences, and a similar digest is being prepared in the economic field. Funds for the cost of the survey have been provided by the Carnegie Corporation of New York.

Academic Assistance Council

THE second annual report of the Academic Assistance Council, published on July 20, contains a statistical summary of the present position of the 1,300 German university teachers dismissed as 'non-Aryans' or for political reasons. Approximately 650 emigrated from Germany ; of these, 287 are already re-established in permanent positions and 336 of the others are being temporarily assisted to continue their research. The importance of organised academic

assistance is shown by the fact that of the 287 scholars who have been re-established, 202 are still within the university world. The Council has played an important part in this work, not only within Great Britain by raising during the past year £24,000 for temporary maintenance grants, but also on an international basis by organising a central information bureau. The Council announces that it hopes to continue its information service as long as possible, although it proposes to end its emergency financial grants by July, 1936. It hopes during the coming year to raise funds to create a limited number of research fellowships to retain in Great Britain the services of some of the most distinguished of the displaced scholars. The need for the continuation of the Council's work is evident. During the past two months, 50 more university teachers have been dismissed in Germany, and, as the report points out, "it is impossible for the exiled scholars to regard return to Germany as a possible alternative to further exile". We hope that the Council will receive sufficient financial support to continue its patient work, for it is making a historic contribution to the cause of free learning. Copies of the report may be obtained free on application to the General Secretary, Academic Assistance Council, Rooms of the Royal Society, Burlington House, London, W.1.

Flight Experiments with Compression-Ignition Engines

THE Air Ministry has ordered a number of "Culverin" 720 horse-power heavy oil engines from Messrs. D. Napier and Son, Ltd. It is understood that these are to be used for complete operational tests in large flying boats. Imperial Airways is also interested in the same problem for civil aircraft, and will doubtless be watching these results. The Napier engine is a horizontal water-cooled engine, built under licence from the German Junkers company. The Bristol Aeroplane Co., Ltd., has also developed a compression-ignition engine of the radial air-cooled type, which has actually gained the world's altitude record for aircraft powered with that type of engine. The Diesel type engine has a definite advantage in long-distance flight owing to its smaller oil consumption, but as it is structurally heavier than the petrol engine this advantage is outweighed on short flights. With modern design and performance of heavier-than-aircraft, there is no gain in using it for a flight of less than about eight hours duration. Another major point in its favour is the lessened risk of fire after a crash. Although the fuel oil used is not non-inflammable, its flash point is much lower than that of petrol, and the risk of ignition from flame or hot parts is less. A minor trouble to be dealt with is the lack of facilities for the distribution of this fuel oil at the present time. The oil distributing companies will need considerable additions to their plant before fuel oil will be available upon as world-wide a scale as is petrol.

Polarising Light Filters

THE Eastman Kodak Company, at the ninth International Congress of Photography recently held in Paris, demonstrated a new kind of light polariser, known as the 'Pola filter'. This is made in sheets and may be used to produce effects similar to those obtained with a Nicol prism. Thus when used in pairs, any desired degree of extinction may be obtained by rotating one filter in relation to the other. In photography alone there are many very useful applications for these filters, such as the elimination of surface reflections from glass windows, water, coloured objects (with consequent increased saturation of the colours), the modulation of blue sky brightness without alteration of hue, etc. The comparative cheapness of these filters, and the possibility of manufacturing them in large sizes, opens up a great vista of applications, in which has been suggested their use to combat headlight glare with motor-cars.

Prehistoric India

A DISCOVERY which, if substantiated, holds out promise of great moment for prehistoric archæology in the Near and Middle East, is announced from India. According to a dispatch from Karachi, which appears in *The Times* of July 19, remains of a city of an earlier date than Mohenjo-daro have been discovered alongside the bed of the Indus River at a site known as Kol Deja or Narujadaro in Khaipur State, Bombay. The discovery was made by Mr. Utam Thakur, a research scholar, in the course of survey work. It is stated that shell and earthenware bangles, decorated images and decorative pottery were found. If further investigation should afford ground for accepting the claim that this material represents an earlier stage of civilisation than that already known from the Indus valley, where the earliest city at Mohenjo-daro is dated at about 3300 B.C., it will have a crucial bearing on the problem of the relations of the early civilisations of Sumeria and India. The authorities of Khaipur State have taken measures for guarding the site, and Mr. Thakur is now engaged in seeking financial aid for carrying out systematic excavation in the coming season.

Equipment of a Photo-Elastic Laboratory

A PAPER of the greatest interest to all who contemplate the design and equipment of a photo-elastic laboratory, and indeed of interest to engineers generally, was read to the Junior Institution of Engineers by Prof. E. G. Coker and appears in full, with many illustrations, in the *Journal* of the Institution of April 1935. It was prepared with the view of giving an outline of the essential requirements of a photo-elastic laboratory when a start is being made from the beginning of things and not merely an adjunct to a larger laboratory already well supplied with much of the experimental apparatus and machinery, which can be utilised for photo-elastic work. For this purpose, the paper opens with a concise statement of the elements of photo-elasticity, a subject which might with advantage be taken up much more widely and at an earlier stage than at present, as the elastic properties of materials are of more or less importance to all engaged in technical

work, though of course in a much greater degree to engineers. By its means a considerable advance has been made in our knowledge of the distribution of stress intensities at discontinuities, where very little exact information was previously available. It is particularly useful in the stress analysis of fusion joints, in which it is, as a rule, a fallacy to assume that stress distributions can be determined by applying elementary methods. In this paper, Dr. Coker takes the connexion of two steel plates in line by means of a V fusion weld as a typical example of the incalculable stresses which can be determined by photo-elastic analysis. He describes the apparatus required and concludes with a description of a detached photo-elastic laboratory made by a small addition to a medium-sized house.

The World's Greatest Highway

THE Inter-American Highway from Alaska and Canada in the north to Chile, the Argentine and Brazil in the south, is now, according to an article in *Roads and Road Construction* of February, having its gaps filled in on the maps and plans of engineers. At present, 4,500 miles of its length are passable by motor-cars in all weathers. The finished sections are in Canada, the United States, Mexico and Panama, and parts of all-weather roads are completed in Alaska, Costa Rica, Salvador, Guatemala, Colombia and Brazil. Highways passable in dry weather cover the greater part of the international highway route. The South American portion of the highway offers a great variety of scenery. There are the jungles of Colombia and Brazil, the sea coasts of Peru and Chile, the magnificent heights of the Andes and the broad expanse of the Argentine pampas. A thousand miles of this highway will be at elevations of 5,000–10,000 ft. The international project is to open up a through route for the highway tourist between North and South America. It will be of special value to citizens of the United States living in the Panama zone. The 250 miles of improved road in Panama have already been largely patronised by the residents of the Canal Zone for recreational travel, and a through highway to the north would be very attractive to them. The Central American section makes it possible to open up large areas for agricultural and commercial development and so promote their economic welfare. At present, access is mainly by steamer to the ports and thence by rail, highway or aeroplane. Pan-American Airways provides a service throughout the length of Central America, paralleling the future line of the Inter-American Highway on the Pacific slope of the divide.

Post Office Publicity

THE present-day policy of the Post Office is based on a recognition of the fact that the Post Office is not only a Government Department, but is also one of the largest businesses in Great Britain. In pursuance of this recognition, recent developments have included the establishment of a Public Relations Department, with an organisation for employing all the most modern methods of publicity at its disposal. An interesting account of the policy being followed by this department is given in a recently published pamphlet entitled, "Post Office Publicity". This pamphlet is the eighth of a series of Post Office Green Papers (London: H.M. Stationery Office. 6*d*. net), previous issues of which have dealt with the air mail service and with various aspects of telegraph and telephone communication. The text of the pamphlet has been adapted from a lecture recently given by Sir Stephen Tallents, Public Relations Officer of the General Post Office, and it is illustrated by a selection of photographs and reproductions of posters and pamphlets already issued by the Post Office. This pamphlet shows how recent advances in the arts of press advertising and exhibition display and the arrival of new forms of communication in films and broadcasting have coincided with the growth of the new need of correctly-balanced publicity. The methods by which the Post Office is pursuing these purposes are clearly described. These include press advertising, the supply of posters of high artistic quality for public display and for use in schools, and the participation in public exhibitions of various kinds, and the temporary leasing of shops in important centres for the display of Post Office activities and equipment. Finally, the G.P.O. Film Unit produces and circulates films which illustrate vividly the great variety of Post Office work.

Canalisation of the Upper Mississippi

AN article in the *Scientific American* of February by Mr. S. G. Roberts describes the important work now being done under the United States Army engineers for the improvement of the navigation of the Upper Mississippi River. Some years back it was considered that a channel six feet deep at low water could be maintained by dredging and contraction works, but this proved to be impracticable. In 1931, therefore, it was decided to canalise the whole length of the river between St. Louis and the 'twin-cities' of Minneapolis and St. Paul, a distance of about 650 miles, so as to give a minimum depth of 9 feet. For this purpose, 27 dams are being built, each having locks 110 feet wide and 600 feet long. The dams are provided with spillways and roller gates suitable for contending with fields or floes of ice, which sometimes attain a thickness of 2 feet. The object of the scheme is to provide for the direct shipment of cargoes from Minneapolis and other places direct to New Orleans by means of flotillas of barges which will carry as much as 14,000 tons, and will be towed through the locks without changing formation. The work was begun about three years ago and is expected to be completed in 1938 at a cost of 124,000,000 dollars. "There is every reason to believe," says Mr. Roberts, "that the work now under way will give to the Mississippi valley a trunk-line water route that will mean to the vast region served by it what the Rhine has long been to Central Europe. From Minneapolis to the sea, the Mississippi has a length of 1,950 miles; and the run from Minneapolis to New Orleans is 1,840 miles.

From the head of navigation on the Rhine to the sea, the distance is 445 miles. Therefore the Mississippi offers a water outlet to a far more extensive region than does the Rhine; and the potential wealth of the American domain is infinitely greater and in some respects more varied."

Cold-Storage Plant in Madrid

WITH the aid of cold-storage plant it is possible to regulate the supply of perishable foodstuffs to a city so that, whatever the season, the supply may be sufficient. A privately owned cold-storage building has been erected in Madrid with this end in view. O. Rhunke gives a description of the plant used in this building in the *Escher-Wyss News* of April. A five-storied building was constructed in the immediate vicinity of the principal markets, with the railway track on one side and the Calle de Toledo on the other. The level of the railway is 23 ft. above the level of the street, so that goods are unloaded from the railway into a chute and delivered into the street from the ground floor. Ten thousand cubic metres are provided for storage for eggs, fruit and fish. The main cooling is by conditioned air with brine-circulated cooling in addition. The temperature and humidity of all the cooling rooms have to be kept within prescribed limits. The used air is cleared out several times every day and ozonising is employed. Special care has to be taken to prevent any interruption of the cooling process taking place. A cooling capacity of thirteen million British thermal units per day is required. It was at first thought that such a spacious building would considerably exceed the needs of the city, but three months after the opening practically all the space was utilised.

East Malling Research Station

THE twenty-second annual report, for the year 1934, of the East Malling Research Station, has just been published (pp. 241. 4*s*. net. May 1935). The Station is maintained by the Kent Incorporated Society for Promoting Experiments in Horticulture, with various grants from the Ministry of Agriculture and Fisheries. A 22-page supplement describes the more administrative side of the Station, and leaves the main volume free to set forth the research findings during the past year. These are, perhaps, even more numerous than usual, for a determined effort has been made to elucidate more fully the problems of insecticides and fungicides. Section 1 of the report describes the experimental farm, and is contributed by Messrs. J. Amos, F. H. Beard, M. H. Moore and A. C. Painter, with a foreword by the director, Mr. R. G. Hatton. Section 2 is a general review of research work, with summaries of papers published during the year. It is compiled by numerous members of the staff. The third section, on preliminary research reports, occupies most of the volume. Truly is the East Malling Research Station justifying its comparison, voiced by H.R.H. the Duke of York, to a standard apple tree, which, once established on good soil, would "continue to flourish and yield excellent fruit".

Farm Machinery

THE favourable reception that attended the publication of the first volume of "Farm and Machine" issued by the Institute for Research in Agricultural Engineering, Oxford, last year, has led to the decision that an annual issue would be justified. Vol. 2, which has recently appeared (2*s*. 6*d*.), contains like its predecessor the report of the Institute for the year under review and also a collection of miscellaneous papers on agricultural engineering. The chief event of the year has been the removal of the Institute into its new quarters in Parks Road, a building well suited for the indoor work and provided with excellent workshop and stores accommodation. The testing of various new types of agricultural machinery naturally takes a prominent place in the work of the Institute, but research on the theoretical side is also carried out, from which important advances have already been made. The titles of some of the miscellaneous articles such as market garden tractors, farm electricity tariffs, the mode of action of mole drains, sugar beet harvesting, implements for regenerating grassland need only be quoted to show that the volume is likely to be of help and interest to a wide section of the farming community.

Rare Developmental Condition in a Boy

A NOTE by Science Service, of Washington, D.C., states that a 'dog-boy' four years old is living in Kharkov, U.S.S.R. His face and body are entirely covered with long blond hair, coarse and a little wavy. The child is otherwise normal mentally and physically except for rickets, which is being treated in the hospital. The relatives are all normal so far as known. This very rare condition is known as hypertrichosis universalis. Some thirty such families have been recorded, most of them from Russia. In certain cases reported from India, the hair was dark. The condition is a developmental defect, in which the prenatal lanugo is not shed. It may be accompanied by faulty teeth and nails. Once the condition has appeared, it is likely to recur in the next generation. An effort should be made to determine whether the family producing this child is related in any way to the previously recorded Russian families.

Bibliography of Seismology

IN a recent issue of NATURE (**135**, 1070; June 29), a brief notice was given of the "Bibliography of Seismology" for the year 1934 prepared by the Dominion Observatory of Ottawa. In that note, it was pointed out that Great Britain is not represented in the list of collaborators. We have received a letter from Dr. F. J. W. Whipple, Kew Observatory, in which he suggests that this omission may be taken to imply that the works of British seismologists are ignored in the Bibliography, and he states that in the last quarterly number there are seven references to such publications. On the other hand, in the United States, there are eleven collaborators, who refer to forty memoirs written in that country. The test as regards completeness is not, however, the actual number of memoirs noticed, so much as the

percentage of the total number published that are entered in the Bibliography, and this percentage obviously depends on the number of contributors. In the absence of collaborators, memoirs are, of course, likely to be overlooked.

World Power Conference

THE annual report for 1934 of the World Power Conference, 36 Kingsway, London, W.C.2, records that the transactions of the Scandinavian meeting held in 1933 have been published in seven volumes. The subjects discussed centre round the power problems of large-scale industry and of land and sea transport. The Chemical Engineering Congress will be held in London on June 22–27, 1936, and will be a sectional meeting of the World Power Conference. After preparatory work extending over seven years, it is hoped that tables of international statistics on a strictly comparative basis will be published this year.

Conference of Empire Survey Officers

THE Third Conference of Empire Survey Officers opened in London on July 23 and will continue in session until August 2. The Conference is not open to the public, but an official report of its proceedings will be published in due course. Representatives of Canada, the Commonwealth of Australia, the Union of South Africa, the Irish Free State, India and Northern Ireland, and of about twenty Colonial dependencies, as well as by representatives of various interested departments, societies and institutions in Great Britain, are attending the Conference. The principal object of these gatherings, of which the two earlier ones were held in 1928 and 1931 respectively, is to afford opportunities for surveyors from overseas to obtain and exchange up-to-date information as to the progress made in survey matters, and for discussions on questions of general interest to surveyors.

IN opening the Empire Survey Conference on July 23, Mr. Malcolm MacDonald, the Secretary of State for the Colonies, expressed his pleasure at being able to welcome at the Conference not only representatives of the various Colonies, Protectorates and Mandated Territories, but also representatives of the majority of the self-governing Dominions, of India, and of Northern Ireland. He referred to some of the subjects to be discussed, such, for example, as trigonometrical and topographical surveying, and various aspects of air survey work. Continuing, Mr. MacDonald said, "Another question which appears on your agenda is that of the co-ordination of African surveys. I need hardly emphasise the importance of this, but I should like to express the hope that this Conference will be able to work out an agreed plan for co-ordination in the future. Closely allied with this is the question of the completion of the Arc of the 30th meridian. The possibility of completing this important work at the earliest possible moment is kept continually in mind." Brigadier MacLeod, the Director General of the Ordnance Survey, who was asked by Mr. MacDonald to preside over the Conference, then thanked the Secretary of State on behalf of the delegates for coming to open the Conference and emphasised the value of periodical Conferences of this nature.

ASLIB

THE twelfth annual conference of the Association of Special Libraries and Information Bureaux is to be held on September 20–23 at St. John's College, Cambridge. According to the preliminary programme, Sir Richard Gregory will deliver his presidential address on September 20 and will speak on the "Interpretation of Science". Mr. J. D. Cowley, director of the University of London School of Librarianship, and others will deal in a symposium with special librarians and their problems, Sir Stephen Gaselee, of the Foreign Office Library, will describe libraries and special sources of information in Government departments, and Mr. B. M. Headicar, of the British Library of Political and Economic Science, will deal with the use of reference books. "What Industry expects from Public Libraries" is the title of a paper by Mr. R. Brightman, of Imperial Chemical Industries, Ltd., while Miss E. W. Parker, of the Mond Nickel Co., Ltd., inquires into the use that industry and commerce make of the public libraries in the London area. Further particulars about the meeting can be obtained from the Secretary, ASLIB, 16 Russell Square, London, W.C.1.

The Third International Congress of Soil Science

SOME four hundred delegates, from twenty-five foreign and twenty British countries, will assemble at Oxford for the Third International Congress of Soil Science on July 30–August 7. The delegates will be welcomed by the Vice-Chancellor of the University at the opening session, and will be entertained by the Government at a dinner in Christ Church Hall on July 31. The meetings have been arranged so that questions of wide interest will be discussed in the mornings at plenary sessions, and more specialised ones in the afternoons at Commission sessions. Sir John Russell will deliver the presidential address on "The Place of Soil Science in Agriculture", and Prof. G. W. Robinson will present a general survey of British soils. The plenary session of Commission IV —Soil Fertility—promises to be of particular interest. Prof. E. A. Mitscherlich will describe the co-operative work developed and organised by him in Germany to test his physiological methods of determining fertility, Prof. R. A. Fisher will outline the principles of his well-known methods of field experimentation as used in England, and Prof. O. de Vries will describe fertility measurements in the tropics with special reference to work in the Netherlands Indies. Other papers likely to attract attention are by Prof. F. Hardy on tropical soil types, by Dr. Brüne on the cultivation of moorland, and by Prof. Lowdermilk on the measures now being adopted in the United States for the control of soil erosion. The programme covers the whole field of pure and applied soil science, and includes a number of excursions of both scientific and scenic interest in the neighbourhood of Oxford.

Beit Fellowships for Scientific Research

THE Trustees of the Beit Fellowships have awarded the following fellowships for research at the Imperial

College of Science and Technology, during the academic year 1935–36: Extensions of fellowships already satisfactorily held for one year to :—Dr. J. Bell, for research in fuel technology—"A spectrographic investigation of hydrocarbon combustion"; Dr. H. I. Stonehill, for research in chemistry—"The applicability of the modern theories of strong electrolytes due to Debye, La Mer, Bjerrum, Davies, etc., and the measurement of the E.M.F. of certain cells"; and Mr. J. R. Tillman, for research in physics on "Electron diffraction". New fellowships for one year, renewable for a second year, to :—Mr. R. Walls, of the University of Liverpool, for an investigation of the metamorphic rocks of north-east Scotland, under Prof. P. G. H. Boswell; Mr. E. W. Hewson, of the Mount Allison University, Sackville, Canada, and the University of Toronto, for research in meteorology, more especially the detailed structure of discontinuities between air masses as occurring in England and Canada, under Prof. D. Brunt; Mr. J. E. Carruthers, of Emmanuel College, Cambridge, for the study of primary photochemical processes and oxidation, applied to kinetics of gas reactions in general, under Prof. W. A. Bone.

The Sky in August

MERCURY passes through superior conjunction on August 10, after which date the planet is once more an evening object. Venus attains its greatest brilliance on August 3, the stellar magnitude then being $-4{\cdot}2$. The planet is now moving towards the sun, and will be difficult to pick up with the naked eye at the end of the month. Mars is still conspicuous in the evening sky, but is decreasing in brilliance, from $+0{\cdot}6^{m}$ to $+0{\cdot}8^{m}$ during the month. This planet is moving towards Jupiter, and will be in conjunction with it on August 27 at 23h., Mars being $2{\cdot}2°$ S. Jupiter is much the brighter of the two, its stellar magnitude declining from $-1{\cdot}7^{m}$ to $-1{\cdot}5^{m}$ during August. Saturn is now rising before midnight, and will be in opposition to the sun on August 31. The stellar magnitude declines from $-0{\cdot}02^{m}$ at the beginning of the month to $0{\cdot}00^{m}$ at the end of the month. It is interesting to inquire whether there is any prospect of seeing all five of the naked-eye planets this year. Venus and Saturn make their closest approach in Right Ascension on August 18, when the two planets are 11h. 16m. 37s. apart. On account of their southerly declinations, they will not be simultaneously visible at Greenwich, or at any station north of terrestrial latitude 39° N. Observers at stations south of this limit will be able to see four of the five naked-eye planets at the same time. Venus goes off as Mercury comes on, but it may be possible to pick out both Mercury and Venus in the sunset at a southern station just after Saturn has risen, the best chance of success being right at the end of the month.

Announcements

IT is announced in *Science* that Dr. R. H. Fowler, Plummer professor of mathematical physics in the University of Cambridge, has been appointed visiting lecturer in mathematics at Princeton University for the second term of next year.

THE annual autumn meeting of the Institute of Metals will be held in Newcastle-upon-Tyne on September 9–12, under the chairmanship of Dr. Harold Moore, president of the Institute. The Autumn Lecture will be delivered on September 9 by Dr. H. W. Brownsdon, who will take as his subject "Metal Melting—Its Effect on Quality"; the lecture will be followed by a discussion. Further information can be obtained from the Secretary, Institute of Metals, 36 Victoria Street, London, S.W.1.

A SPECIAL train has recently been organised in Germany for the rapid conveyance of first aid to any place where a great disaster such as a flood or earthquake has taken place.

ERRATUM. Prof. Hans Falkenhagen writes, in reference to the letter in NATURE of May 18, p. 830, entitled "Compressibility of Electrolytic Solutions", by Ch. Bachem and himself, that the expression $k = Ac + Bc^{3/2}$, as written by them, is incorrect. It should read $k = C + Ac + Bc^{3/2}$.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

A technical officer at the Royal Aircraft Establishment, South Farnborough, Hants, to assist in the investigation of aircraft problems relating to aerodynamics, strength and stiffness—Chief Superintendent, Royal Aircraft Establishment, South Farnborough, Hants, quoting A. 734 (July 29).

An assistant (Grade II) at the Building Research Station for work on problems connected with painting and decoration—Establishment Officer, Department of Scientific and Industrial Research, 16 Old Queen Street, London, S.W.1 (July 31).

A lecturer in mathematics with subsidiary biology at the Saltley Church of England Training College for Schoolmasters, Birmingham—The Principal (Aug. 1).

An engineer officer for the Indian Mercantile Marine Cadets Training Ship *Dufferin*—High Commissioner for India, General Department, India House, Aldwych, London, W.C.2 (Aug. 1).

An assistant lecturer in inorganic and physical chemistry, University College of the South West, Exeter—The Registrar (Aug. 5).

A full-time and a part-time graduate assistant in the Department of Mechanical Engineering, Guildford Technical College—Director and Secretary, Technical College, Park Street, Guildford.

Part-time lecturers in automobile engineering, drawing and design, and workshop processes in the Mechanical Engineering Department, The Polytechnic, Regent Street, London, W.1—Director of Education.

An assistant lecturer in civil engineering in the Battersea Polytechnic, London, S.W.11—The Principal.

A lecturer in plant pathology and zoology at the Swanley Horticultural College for Women, Swanley, Kent—The Principal.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 148.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Thermo-electric Effect and the Supra-conducting State

USING the supra-conducting galvanometer described in a previous issue of NATURE[1], we have tried to measure the thermo-electric effect of lead and tin when they were both supra-conducting. The method used to obtain a temperature difference between the junctions was similar to that described by Borelius, Keesom, Johansson and Linde[2].

One junction, A, was immersed in liquid helium, and its temperature was regulated by controlling the pressure over the liquid. The second junction, B, was enclosed in a metal container which was also immersed in the liquid helium; this container could be evacuated independently of the outer chamber containing liquid helium and so isolated thermally except for the metal connexions from B to the outside. The temperature of the junction B was first brought to the same value as A by the thermal conduction of the low-pressure helium gas in the B container; the temperature of B, which was measured by a helium gas thermometer, could be raised by means of a constantan heating coil.

With the temperature of A at 3·8° K. and B at a somewhat higher temperature, a current was registered by the galvanometer. With A at 2·0° and B anywhere between 2·0° and 3·7°, no current was indicated. When B was raised above 3·7°, while A remained at 2·0°, a current flowed in the galvanometer.

Since the supra-conducting point of lead is 7·2° K. and that of tin 3·7° K., we can conclude from this experiment that no thermo-electric effect exists when both junctions are in the supra-conducting state, but the effect comes in when either one of the junctions is raised above the supra-conducting point of one of the metals.

The Masses of Be^8 and C^{12}

THE recent set of nuclear masses proposed on the basis of disintegration experiments[1] includes the values 4·0034 for He^4, 8·0071 for Be^8 and 12·0027 for C^{12}. From these values it follows that the binding energy of two α-particles is either slightly negative or else very small (less than 200,000 volts) whereas that for three α-particles is quite large (7×10^6 volts).

This seems surprising, but may be obtained simply without assuming anything more than a Gamow type of interaction between two α-particles. Thus, taking this interaction potential in the form

$$V = 4e^2/r \,, \; r > r_0 \,;$$
$$= -c \quad , \; r < r_0 \,;$$

with c and r_0 related in such a way as to give a certain small value for the binding energy of Be^8, one finds that the observed mass of C^{12} may be obtained by suitable adjustment of the single parameter r_0. For example, taking 200,000 volts for the binding energy of Be^8, a value of r_0 slightly greater than 2×10^{-13} cm. will give the observed mass of C^{12}. Smaller values of r_0 than this give rise to increasingly larger binding energies than the observed, and these results are not critically dependent on the value assumed for the binding energy of Be^8. More precise limits for r_0 will be fixed by consideration of heavier nuclei.

We have here a further example of the sensitivity of binding energies for short range fields to changes in the field parameters.

Deposition of Artificial Radio-Elements by Electrochemical Exchange

THE method of preparation of sources of some natural radio-elements (polonium, radium *C*, etc.) on metallic plates by electrochemical exchange and the advantages that it presents are well known. I have tried to apply the method to the separation of radio-copper (period 10 hr.) from zinc. Preliminary experiments have shown that, of the metals nickel, tin, lead and iron which are in the series of tension between copper and zinc, lead gives the best results. The following method has been adopted:

8–12 gm. of zinc powder is attacked by concentrated hydrochloric acid, after irradiation by neutrons, until a residue of 200–300 mgm. remains. This is separated by filtration from the solution. Measurements made with the aid of a Geiger-Müller counter show that *practically all the activity is concentrated on the non-dissolved zinc*. The latter is now dissolved separately in concentrated hydrochloric acid and diluted with about two volumes of distilled water. A plate of lead of suitable dimensions and with one side covered by an insulating material is then rotated in this solution. After 30 minutes, more than half the radio-copper is deposited on the plate.

The method permits the preparation without co-precipitant and, consequently, without absorption of activity, of strong sources of radio-copper in extremely thin layers. Unfortunately, it is not applicable to other known artificial radio-elements, since the elements obtained up to the present by neutron bombardment are generally either isotopes of the elements bombarded or electrochemically less noble.

Disintegration Constant and the Upper Limit of the Continuous β-Spectrum

SARGENT[1] discovered the relation between the disintegration constant of the radioactive elements which decay by emitting a β-particle and the upper limit of the continuous β-spectrum. He found that in the diagram obtained by plotting the logarithms of the disintegration constants against the logarithms of the upper limits, a straight line can be drawn through the points for RaE, $MsTh_2$, ThC and RaC, and a curved line through the points for RaD, UX_1, ThB, AcC″, ThC″ and UX_2. The points for AcB and RaB do not fall on either of these curves.

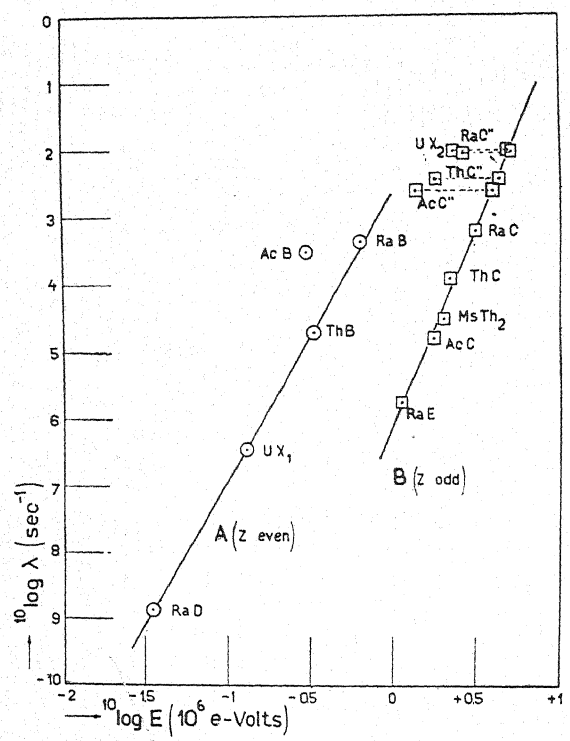

FIG. 1.

Recently, I remarked[2] that a simple diagram is obtained if the upper limits are plotted against $M - 1{\cdot}5Z$ (M = mass number, Z = charge number). From this diagram the upper limits of the elements AcC and RaC″, which are not yet measured, can be estimated with good approximation. Using the two values obtained in this way ($1{\cdot}8_1 \times 10^6$ and $2{\cdot}6_7 \times 10^6$ electron volts respectively) to complete Sargent's diagram, one finds that the point for AcC falls on the straight line and that for AcC″ on the curved line. In the same communication I directed attention to the fact that the upper limits are generally higher for the elements with odd charge number, than for those with even charge number. From this fact the question arose whether the difference between the even and the odd elements might be of interest for the interpretation of Sargent's diagram.

That this is really the case can be seen from Fig. 1, in which the diagram is reproduced completed with the points for AcC and RaC″. Instead of the curved line mentioned above, a straight line is drawn through the points for RaD, UX_1, ThB and RaB. Now, in the diagram, three groups of points are to be distinguished: (1) Points for the elements with *even charge number* which, with the single exception of AcB, fall on the straight line A; (2) points for the elements with *odd charge number*, RaE, AcC, $MsTh_2$, ThC, RaC, which fall on the straight line B; (3) points for the elements with *odd charge number* AcC″, ThC″, RaC″, UX_2.

If λ is expressed in sec.$^{-1}$ and E in 10^6 e.-volts (and if logarithms to the base of ten are used) the straight lines correspond to the formulæ:

$$A\ (Z \text{ even}):\ \log \lambda = -2{\cdot}63 + 4{\cdot}35 \log E = -2{\cdot}63 + 1{\cdot}45 \log E^3.$$

$$B\ (Z \text{ odd}):\ \log \lambda = -6{\cdot}11 + 5{\cdot}80 \log E = -6{\cdot}11 + 1{\cdot}45 \log E^4.$$

If the energy of an electron, $m_0c^2 = 0{\cdot}510_4 \times 10^6$ e.-volts, is used as unit of energy, these equations become:

$$A\ (Z \text{ even}):\ \log \lambda = -3{\cdot}90 + 1{\cdot}45 \log E^3.$$
$$B\ (Z \text{ odd}):\ \log \lambda = 2(-3{\cdot}90 + 1{\cdot}45 \log E^2).$$

It may be of interest to remark that the four elements of the third group are all 'branch products'. Further, it was found, as is indicated in Fig. 1 by the dotted lines, that the points belonging to these four elements all can be brought on to the straight line B by adding $2{\cdot}6_3 \times 10^6$ e.-volts to the value of the upper limit. This can scarcely be a mere chance. Moreover, this energy of $2{\cdot}6_3 \times 10^6$ e.-volts is just equal to the energy of the intense γ-radiation which is emitted by ThC″, and is the hardest γ-radiation known. A γ-radiation of about the same energy is also observed with RaC + C′ + C″. Here it is generally ascribed to RaC, but the possibility does not seem excluded that it has its origin in the nucleus of RaC″. Perhaps it would repay the trouble to look for such a hard γ-radiation also with UX_2 and AcC″.

Diffraction of X-Rays and Electrons by Carbon Tetrachloride Vapour

RECENT electron-diffraction investigations[1] of the molecular structure of gaseous carbon tetrachloride give values of the interatomic distances, which are appreciably lower than those obtained in earlier electron-diffraction measurements and those obtained by Bewilogua[2] from X-ray photographs. This discrepancy of about 4 per cent is so important that it cannot be explained by the probable errors given by the authors. As, moreover, carbon tetrachloride is generally used as a standard substance for testing the apparatus, it

seemed to us to be of interest to compare X-ray and electron-diffraction results from as wide a field as possible with the corresponding theoretical calculation, using in both cases the most trustworthy experimental methods.

The electron-diffraction apparatus used for this purpose was that constructed by de Laszlo[3]. We developed a narrow tube system, which absorbs the primary electron beam as soon as it leaves the vapour-jet system. This made it possible to reduce the pressure in the vapour-jet system and thereby all disturbing scattering effects. Perfect microphotometer records could be obtained of the photographic plates by rotating them at high speed. All influence of grain and dust was thus avoided. The theoretical scattering curve was obtained in the usual way, introducing the atomic form factors of James – Brindley and Heisenberg – Bewilogua's S-values for inelastic scattering. Supposing the atomic part of the theoretical intensity curve (monotonic curve, representing the total intensity without the details concerning molecular structure) rendered correctly by the corresponding experimental values, the influence of molecular structure on the atomic part of intensity could be compared with good accuracy.

We found that, at the first minimum and maximum, good agreement of theory and experiment could be obtained. At the fifth apparent maximum, however, the theoretical curve was more prominent than the record indicated. This discrepancy may be explained by the influence of thermal vibrations, which is rather important in this region. Using James's formula[4] for this correction, we found that excellent agreement could be obtained. However, the detection of this thermal vibration effect had no influence on the interatomic distance measurements. The study of microphotometer records and the generally used visual measurements of ring diameters at large scattering angles both gave values for the chlorine-chlorine distance of $2{\cdot}86 \pm 0{\cdot}03$ A. and for the carbon-chlorine distance $1{\cdot}75 \pm 0{\cdot}02$ A. These values are in excellent agreement with those mentioned previously[1].

Up to the present time, the X-ray distance measurements of Bewilogua have never been controlled. Meanwhile, one of us[5] has shown, however, that a more satisfactory agreement of intensity values could be obtained, if monochromatic X-rays were used; but the large volume of gas effective in scattering did not allow of the determination of trustworthy interatomic distances. An improved form of this arrangement with a circular mica window closing the vapour tube, combined with a powerful X-ray source, made it possible to reduce considerably the scattering volume of gas and to avoid the corresponding correction. With copper $K\alpha$ radiation, two maxima and three minima, with molybdenum $K\alpha$ radiation, five maxima and minima could be measured. The agreement between microphotometer records and corrected theoretical intensity curves was satisfactory in both cases and accurate distance measurements could be obtained. The mean values from several photographs are: $2{\cdot}85 \pm 0{\cdot}03$ A. for the Cl-Cl distance and $1{\cdot}74 \pm 0{\cdot}02$ A. for the C-Cl distance. These values are appreciably lower than those given by Bewilogua, and it seems that the experimental improvements effected are the reason for it.

The present investigation shows that the diffraction of X-rays and electrons by carbon tetrachloride agrees with theoretical calculation and both lead to the same values of interatomic distances.

Full details will be published shortly in the *Physikalische Zeitschrift*.

Interaction between Acetylcholine and Sterols in Tissues

WE have recently carried out some experiments on the form of the contraction given by the gastrocnemius muscle of a winter frog[1] in response to a single electrical stimulus. In certain circumstances, of which the most important is the presence of thyroxine at slightly above the physiological concentration in the Ringer's solution in which the muscle is bathed, the muscle gives an abnormal prolonged contraction if either acetylcholine or one of several sterols is added to the medium. This abnormal contraction greatly resembles a tetanic contraction in form. It is of exactly the same type whether it is produced by the addition of acetylcholine or of a sterol. Further, if both acetylcholine and a sterol are added to the medium together, in a proportion which is different for different sterols but is well-defined for each, the contraction remains a normal twitch and shows no tendency to become prolonged. So long as this proportion between the concentrations of acetylcholine and sterol in the medium is maintained, the concentrations of both may be altered over a wide range and the contraction will remain a normal twitch.

These conclusions are illustrated by the results of the following experiment. A muscle was set up in a modified Ringer's solution containing acetylcholine at a concentration of $1/10^6$ by weight. After 60 min. it responded (to stimulation of its nerve by a single shock) with a prolonged contraction of 1·4 sec. Ergosterol $1/10^5$ was then added to the medium, which was otherwise unaltered. In ten minutes the contraction had returned to a normal twitch and it remained thus for 20 min., when it again lengthened. At 60 min. it was 2·35 sec. long. The concentration of acetylcholine was then raised to $1/10^5$, and the contraction again shortened and afterwards again lengthened to a prolonged contraction of 1·7 sec. Finally, the concentration of ergosterol was raised to $1/10^4$. In a further 60 min. the contraction had once again returned to a normal twitch. Later, it again lengthened to a prolonged contraction of 1·5–1·9 sec.

Results such as these have been obtained in many experiments. They show, first, that the normal twitch may occur with very different concentrations of acetylcholine and sterol. Secondly, it seems that the only way that the return to the normal twitch and the later resumption of the prolonged contraction after each addition of acetylcholine or sterol can be interpreted is to suppose that a balance between the concentrations of acetylcholine and sterol in the tissue is necessary if the contraction is to have the

form of a normal twitch. After each addition, the added substance diffuses into the tissue, and this balance is first re-established (when the contraction becomes a normal twitch), and then overturned on the opposite side (when the prolonged contraction is resumed). We do not wish to draw any conclusions from the actual concentrations of acetylcholine added to the medium. This substance breaks down rapidly in solution and it is probable that in such experiments as these the concentration in the muscle is not equivalent to that added to the medium.

So far, only a few sterols have been used in these experiments, but all those we have used are active to a greater or less extent. Cholesterol, both as supplied by The British Drug Houses and as a highly purified sample, was found to have one fifth the activity of ergosterol: di-hydrocholesterol had one tenth the activity of cholesterol. A few other sterols have been used. All these sterols were suspended in the medium with lecithin, which was itself shown to be inactive.

In view of these results, we have thought it worth while to investigate the action of sterols on the beat of the frog's heart, in order that any action of these substances might be compared with the well-known action of acetylcholine. We have obtained results which are parallel to those of our experiments on muscle. When the sterol is placed in the medium circulating through a heart, the beat is reduced in height and slowed and, if the quantity of the sterol is sufficient, the heart is stopped for a time. The reaction of the heart is precisely similar to its reaction to acetylcholine. Frogs' hearts vary greatly in their sensitivity to acetylcholine and sterols, and for this reason it is not so easy to balance a concentration of acetylcholine against one of a sterol in these experiments as in those on muscle. But, if the quantities of acetylcholine and sterol which are necessary to produce stoppages of equal length in the same heart are determined, and these quantities of both substances are then placed together in the medium, the change in the heart beat is very much less than is produced by either separately and often there is no change at all. As in the experiments on muscle, it seems that if a certain proportion is maintained between the concentrations of acetylcholine and sterol, the normal behaviour of the tissue is not disturbed, although the concentrations of both acetylcholine and sterol in the tissue are greatly altered.

Since both acetylcholine and sterols are natural constituents of animal cells, we think that these results suggest that, at least in the phenomena which we have investigated, the sterols play a part in the same chemical processes as those in which acetylcholine is concerned; and that a definite proportion between the concentrations of acetylcholine and sterols in the tissue is necessary for its normal functioning. Since several sterols are active in these phenomena, it is clear that many of the sterols can replace each other in this as in their other actions, and that the activity of any one sterol is no proof that it is the natural active substance.

Estimation of Ascorbic Acid by Titration

UNDER this title McHenry and Graham[1] have published an investigation on the ascorbic acid content of raw and cooked foodstuffs. They found in the case of cauliflowers, carrots, parsnips, beets and potatoes more ascorbic acid in the cooked than in the raw food (determined by the method of Birch *et al.*). They believe the increase is due to the setting free of bound ascorbic acid, perhaps from an ester. In the case of certain plant tissues, then, a simple extraction and titration procedure does not give the complete value of ascorbic acid, but only measures the free acid.

From the following observations (Tables I and II) I conclude that this view is not correct, and that the increase by cooking is not a real increase; in reality, after cooking the ascorbic acid content decreases.

Table I.

mgm. Vitamin C in 10 gm. of a single potato under various conditions of extraction.

1.	Ground up in a mortar under trichloroacetic acid (3 per cent)	3·05
2.	Extract (1) after mercuric acetate and hydrogen sulphide treatment[2]	3·11
3.	Ground up without trichloroacetic acid and then diluted with trichloroacetic acid	0
4.	Extract (3) after mercuric acetate and hydrogen sulphide treatment	3·11
5.	Ground up under trichloroacetic acid after addition of 2·25 mgm. ascorbic acid	5·36
6.	Extract (5) after mercuric acetate and hydrogen sulphide treatment	5·35
7.	Ground up without trichloroacetic acid after addition of 2·25 mgm. ascorbic acid and then diluted with trichloroacetic acid	0·36
8.	Extract (7) after mercuric acetate and hydrogen sulphide treatment	5·35

Table II.

mgm. Vitamin C in 10 gm. of a single potato before and after cooking.

1.	Ground up under trichloroacetic acid before cooking	3·18
2.	Extract (1) after mercuric acetate and hydrogen sulphide treatment	3·21
3.	After cooking for 45 min., then ground up with trichloroacetic acid	2·67
4.	Extract (3) after mercuric acetate and hydrogen sulphide treatment	2·59
5.	After cooking for 45 min., then ground up without trichloroacetic acid and diluted with trichloroacetic acid	2·59
6.	Extract (5) after mercuric acetate and hydrogen sulphide treatment	2·48
7.	Ground up, cooked for 45 min., then diluted with trichloroacetic acid	0
8.	Extract (7) after mercuric acetate and hydrogen sulphide treatment	0·13

Hence it follows that the apparent increase must be attributed to the destruction of an oxidase present in some vegetables*, which changes the reduced ascorbic acid into the reversibly oxidised state when the vegetables are ground up. Therefore it is necessary to reduce the extract with hydrogen sulphide after mercuric acetate precipitation[2]. This oxidase is not active in 3 per cent trichloroacetic acid solution. So the discrepancy may be caused by omitting or adding too small quantities of trichloroacetic acid at the moment of grinding up the vegetables. The oxidase is destroyed by cooking, so that in an extract of cooked vegetables the vitamin is not oxidised.

Finally, attention must be directed to the fact that when determining the ascorbic acid content in blood, an analogous phenomenon takes place. The ascorbic acid in the blood is present in the reduced state. This is proved by the fact that the serum extract before and after mercuric acetate and hydrogen sulphide treatment contains the same amount of

* Tauber and Kleiner have isolated an 'ascorbic acid oxidase' from Hubbard squash (*Proc. Soc. Exp. Biol. and Med.*, **32**, 577; 1935), Szent-Györgyi a 'hexoxidase' from cabbage leaves (*J. Biol. Chem.*, **90**, 385; 1931). The oxidation of ascorbic acid by potato juice is due to the polyphenoloxidase, which oxidises phenol to quinone, then the quinone oxidises the ascorbic acid (Szent-Györgyi und Vietorisz, *Biochem. Z.*, **233**, 236; 1931).

ascorbic acid. However, in the presence of erythrocytes, the ascorbic acid is reversibly oxidised when precipitating the blood with trichloroacetic acid. Hence only after reduction with hydrogen sulphide (after mercuric acetate precipitation) can the quantity of ascorbic acid be determined[3].

Proteolytic Digestion in the Ammocœte Larva

MISS ALCOCK[1], in an early publication on digestion in the ammocœte larva, stated that extracts of the liver, alimentary canal and skin showed proteolytic activity of the peptic type. More recently, however, Berrill[2,3] has described an enzyme of the tryptic type in the 'liver' and skin (hatching enzyme) of ascidians, and in view of the phylogenetic relationship between these forms, Miss Alcock's work, which was carried out before the realisation of the importance of *p*H control, clearly demands reconsideration.

In the course of investigations, still in progress, into the problems of digestion in the Cyclostomata, I have found that proteolytic digestion in the ammocœte larva of the brook-lamprey is in fact markedly similar to that of the Ascidiacea, for in extracts of the anterior end of the so-called mid-gut (by which is meant the main wide portion of the intestine) and of the skin, it is possible to demonstrate, using as substrates casein (for formol – caustic soda titration) and gelatine, strong proteolytic activity of the tryptic type, the optimum being at about *p*H 8. The intestinal extract is stronger than that of the skin. No such effect is obtainable from extracts of the liver or of the remainder of the mid-gut, although all four extracts show a very weak proteolytic activity in an acid medium of a *p*H at least as low as 1·5; the most reasonable explanation of this latter effect would seem to be that it is due to the presence of an autolytic tissue enzyme.

With regard to the localisation of the digestive enzyme in the mid-gut, it may be noted that recent work (Boenig[4], Cotronei[5] and others) on the so-called 'pancreas' of the Cyclostomata appears to have established firmly the fact that this organ is exclusively endocrine in nature, Cotronei pointing out that the zymogen cells must therefore still be confined to the intestinal epithelium. Now Brachet[6] had previously directed attention to the presence in the epithelium at the anterior end of the mid-gut of specialised granular cells, characterised especially by the possession of very large nucleoli, and had suggested that these might represent a localisation of zymogen cells. It will be seen that my results indicate that the proteolytic enzyme of the mid-gut is produced in precisely this region.

Guanine in the Excreta of Arachnids

SINCE the work of Gorup-Besanez and Will in 1849[1], it has been classical to regard guanine as taking the place of uric acid as the main nitrogenous end-product of arachnid metabolism. This view is accepted in all the monographs on comparative biochemistry, such as that of von Fürth[2], but it appears to rest wholly on colour tests of uncertain value and deductions from crystal form.

Accordingly, it was thought desirable to examine the Arachnida and their metabolic products with the aid of the specific deaminating enzyme guanase which occurs in mammalian (rabbit) liver and forms xanthine from guanine. A number of different species of spider were examined, and the work will be continued on tropical material in Siam. Here only the experiments on the collected excreta of the common garden spider, *Epeira diadema*, will be mentioned. By this specific method, following the details given by G. Schmidt[3], an average of 12 per cent of the weight of the excreta was found to be guanine. In view of the fact that no separation of the product of the Malpighian tubes from that of the gut was made, this figure is fairly considerable.

This is the first demonstration of the presence of guanine in arachnid excreta using a specific enzyme.

Structure of the Proboscis in Blood-Sucking Diptera

DR. S. K. SEN[1] has expressed the view that the food-canal of blood-sucking Diptera is not formed, as is generally supposed, by the apposition of the labrum-epipharynx and the hypopharynx, but that it is actually the lumen of the hypopharynx itself, a channel which has been regarded hitherto as the continuation of the salivary duct. From the studies I have made it appears to me that this view is quite incorrect. An adequate reply to Dr. Sen would occupy too much space in this journal, but I have fully explained my views in various papers in *Parasitology* (1926, 1928, 1929 and 1932) and I must ask those who are interested in the subject to refer to them.

Dr. Sen says that the labrum-epipharynx is entirely unconnected with the buccal chamber (termed *hyoid* in my papers), but in fact in all the blood-sucking Diptera which I have studied, the epipharynx is continuous posteriorly with the dorsal part of the wall of the hyoid or, if this sclerite is absent, with the anterior membranous wall of the pharynx. The apodemes (termed *stipites* in my papers) do not separate the labrum-epipharynx either from the buccal chamber (hyoid) or from the hypopharynx, since each of them is attached to the postero-lateral part or to the posterior process of the labrum. Furthermore, as regards the statement that the salivary duct terminates at the base of the hypopharynx, this view again appears unsound, since in all blood-sucking Diptera, with the exception of those of the genus *Culicoides*, the common salivary duct penetrates the hypopharynx and opens at its tip[2].

Dissection is of value only for the study of the general structure of the proboscis and its various components; the relation of these to each other, specially in the guttered part of the labium, can only be studied in complete series of transverse sections. It is, moreover, misleading to base any generalisation upon the study of a single species of this large order of insects.

Kinetics of Heterogeneous Catalysis and of Enzyme Action

THE activation of the adsorbate recently described in NATURE[1] was explained by the formation of an adsorption complex $E{-}S^+$ in which the adsorbed molecule S has gained a quantum of rotation-vibrational energy from the surface molecule E. This complex will be dissociated into $E+S^+$ by the supply to it of a quantity of energy equal to that transferred from E to S in the formation of the complex. If the energy of activation of the free molecules S^+ be the critical increment of one of the reactions of the substance S, that reaction will be promoted by the surface of E molecules.

If now the number of molecules in the available surface be represented by E and the molecular concentration of the reactant (assumed to be constant) be represented by S, the initial velocity of formation of the adsorption complex will be k_1SE and at time t the velocity will have fallen to $k_1S(E-x)$, where x is the number of adsorption complexes which have been formed. The velocity of dissociation of these complexes at time t will be $k_2xe^{-Q_1/RT}$, where Q_1 is the amount of energy transferred from surface to adsorbate in forming the complex. If the concentration of S be constant, a stationary state will be established at which the velocity of the reaction promoted by the surface will be given by

$$r = k_1S(E-x) = k_2xe^{-Q_1/RT}.$$

By the elimination of x we have

$$r = \frac{k_1SEK}{k_1S+K}, \text{ where } K = k_2e^{-Q_1/RT}, \text{ and}$$

$$\log \frac{r}{k_1SE-r} = \log \frac{k_2}{k_1S} - Q_1'/T, \text{ where } Q_1' = Q_1/2{\cdot}303R.$$

If now the substance E be itself adsorbed as a unimolecular layer on a surface C with the formation of the adsorption complex $C{-}E^+$, the molecules of E will now be activated, the energy of activation being denoted by Q_2. When these activated molecules adsorb the reactant S there will be formed the adsorption complex $C{-}E{-}S^{++}$, in which the total energy of activation of S^{++} is Q_1+Q_2. This complex will be resolved by the absorption of the energy Q_1 into $C{-}E+S^{++}$ and the de-activated catalyst $C{-}E$ will be reactivated to $C{-}E^+$ by the absorption of the energy Q_2. In this manner a reaction with a total critical increment of Q_1+Q_2 can be promoted by an adsorbed catalyst, the total energy being absorbed from the surroundings in two separate and distinct stages.

By analogy with the above simple case a stationary state will be established, if the concentration of the reactant S be maintained constant, the reaction velocity being given by

$$r = k_1S(E-x-y) = k_2xe^{-Q_1/RT} = k_3ye^{-Q_2/RT}.$$

By the elimination of x and y we obtain the same expression as before, namely:

$$r = \frac{k_1SEK^1}{k_1S+K^1};$$

$$\text{but } K^1 = \frac{k_2k_3e^{-(Q_1+Q_2)/RT}}{k_3e^{-Q_1/RT} + k_3e^{-Q_2/RT}}.$$

$$\text{Since } \frac{e^{-(Q_1+Q_2)/RT}}{e^{-Q_1/RT}+e^{-Q_2/RT}} = \frac{e^{-Q_2/RT}}{1+e^{(Q_1-Q_2)/RT}},$$

the exponential term has a maximum value of $\frac{1}{2}e^{-Q_2/RT}$ when $Q_1=Q_2$. If $Q_1=Q_2$, there will be two exactly similar processes taking place under identical conditions and hence it is legitimate to assume that $k_2=k_3$. On these two assumptions the expression for the reaction velocity is much simplified and may be written in the forms

$$r = \frac{k_1SE \times 0{\cdot}5k_4e^{-Q_2/RT}}{k_1S + 0{\cdot}5k_4e^{-Q_2/RT}}$$

$$\text{and } \log \frac{r}{k_1SE-r} = \log \frac{k_4}{2k_1S} - Q_2'/T,$$

where $k_4=k_2=k_3$, $Q_2'=Q_2/2{\cdot}303R$ and Q_2 is one half the total critical increment of the reaction promoted by the adsorbed catalyst.

It may be suggested that enzyme reactions are of this two-stage activation type, since there is little doubt that the enzyme is adsorbed on the co-enzyme. The virtue of such an enzyme system is due to the fact that it is able to promote within a living organism a reaction the critical increment of which is so large that it cannot otherwise take place with measurable velocity at the temperature of that organism.

The equations and the specificity of enzyme systems will be described more fully in a further communication, but one important conclusion may be stated. Neither the critical increment of a heterogeneous reaction nor that of the de-activation of an enzyme system can be determined directly from measurements of the reaction velocity at two different temperatures, since it is $\log \frac{r}{\text{const.}-r}$ and not $\log r$ which is linear with the reciprocal of the absolute temperature.

Shape of the NO_2 Molecule

IN a recent paper[1], one of us has shown that the available data[2] on the contours of the infra-red bands of NO_2 are most consistently interpreted by a ring-like structure for the molecule, with the O–N–O angle approximately 60°. The theory of directed valency was employed there to provide a possible electronic configuration for this model. Closer investigation of the electronic structure, however,

indicates that a much more probable form has the O–N–O angle in the neighbourhood of 110°–120°.

Dr. R. M. Badger and Dr. G. Herzberg have suggested independently[3] that the wide-angled form is the correct one. The former points out that a ring-like structure would be inconsistent with the low value (641 cm.$^{-1}$) observed for the frequency ν_2, while the latter shows that the fine-structure of the ultra-violet bands[4] indicates a rather flat molecule. On these grounds, they both suggest a re-assignment of the fundamental frequencies as shown in the accompanying table. The object of this re-assignment is to avoid difficulties which would otherwise arise in interpreting the observed contours of the infra-red bands. A discussion of these cannot conveniently be given here.

Fundamental Frequencies of the NO_2 Molecule in cm.$^{-1}$.

Designation	ν_1	ν_2	ν_3
Sutherland	1373	641	1615
Badger and Herzberg	1615	641	1373

We have recently been making a study of the force fields in triatomic molecules, more particularly of the force constant controlling the bending frequency (ν_2), and from it we find that the wide-angled structure for NO_2 is definitely to be preferred. We find, moreover, that the original assignment of the fundamental frequencies seems more likely to be the correct one. This immediately leads to difficulties regarding the contours of the infra-red bands, which Badger and Herzberg's re-assignment was designed to avoid. Since the latter does not, however, resolve all the difficulties, we feel that an extensive and careful re-examination of the contours of the infra-red bands will be necessary before these can be used as a reliable guide to the shape of the molecule.

A full account of these investigations will be published later elsewhere.

Influence of Viscosity Variation on the Rupture of Plastic Bodies

THE term viscosity has frequently been used in a qualitative sense in describing the properties of solids and particularly of metals, but its use in the quantitative sense which has been developed through the study of liquids is a comparatively recent development. Viscosity may be defined quite generally as the ratio of the shearing stress in any plane to the rate of shear or velocity gradient perpendicular to the plane. Thus defined it appears always to be a variable quantity for solids, its value depending on a number of factors, but particularly on the magnitude of the shearing stress. No emphasis appears, however, to have been laid on the importance of the *degree of variability* of the viscosity in relation to the rupture of plastic solids.

The point is most easily explained by reference to 'runny' materials to which standard viscometric methods may be applied: (we avoid the word 'fluid', because this is sometimes taken to imply a constant viscosity). If some golden syrup is sucked up into a tube 10–20 cm. long, and about 1 cm. in diameter, it will run out quite continuously without forming drops. A clay paste, on the other hand, falls from the end of the tube in 'blobs' (they can scarcely be called drops). The surface tension is about the same in the two cases, and its influence is not large owing to the use of a very wide tube. The difference in behaviour must be due to viscosity. It cannot be a question of the absolute magnitude of the viscosities, as these can be considerably changed by altering the concentrations of sugar and clay without making the two materials behave alike. We can only attribute the difference to the fact that while the viscosity of a sugar syrup is independent of the stress, that of a clay paste varies very greatly, particularly in the neighbourhood of its 'yield value'. Soft soap, when warm, will run from such a tube, and has a viscosity which is not constant like that of syrup, but yet is not as steeply variable as that of a clay paste. It is interesting to observe that in falling from the tube this material forms blobs which, if they do not have to fall too far, do not become completely detached from one another. Its behaviour is thus intermediate, as we should expect.

We are not aware that similar reasoning has, as yet, been applied to the behaviour of solids in tension. In the case of flour dough we have developed, for the quantitative measurement of viscosity, a technique which has been considerably extended and improved in co-operative work with Dr. P. Halton of the Research Association of British Flour Millers, and there are strong indications that shortness in a dough is associated with a particularly rapid decrease of viscosity with increase in shearing stress. We have not sufficient personal experience with metals to make any assertion about their behaviour, but we venture to suggest that the rate of decrease of viscosity (as defined above) with increase in shearing stress may be a determining factor in their tensile strength. A general connexion between the manner of rupture and the degree of variability of viscosity may be found to hold even though the underlying mechanism is quite distinct as between different kinds of materials.

In practice, the position is apt to be obscured by factors in addition to shearing stress which influence viscosity. For example, heather (*Calluna vulgaris*) honey if kept in the tube overnight sets to a thixotropic gel which causes it to fall in blobs, whereas after stirring it behaves substantially like syrup. Again, flour dough strain-hardens on extension. As with metals, this delays 'necking' when cylinders of this material are extended.

The behaviour of rubber in benzene differs from both syrup and clay pastes because it has a much longer relaxation time (ratio of viscosity to rigidity modulus). We suggest, however, that such factors, though introducing complications, do not necessarily upset the postulated relationship between the degree of variability of viscosity and the manner of rupture, and that it may prove illuminating in the study of many materials.

Electrical Units and the I.E.C.

SIR RICHARD GLAZEBROOK says[1]: "It is recognised hat in addition to the three accepted units of length, ime and mass a fourth unit is required for the pecification of electrical quantities". Recognised ›y whom? What has happened to the upholders ›f the old doctrine that these three quantities are ›ossessed of some mystical peculiarity in virtue of vhich they are necessary and sufficient as 'funda-nental units'? Is it abandoned; if so, what do those vho held it now believe? Or has a fourth magnitude ›ossessed of this mystical property been found; if ›o, what is it?

Though I may be in a minority of one, I ask leave ›o repeat the conclusions that I have expounded at uch length in my "Measurement and Calculation". f a 'unit' means something fixed by arbitrary choice nd not by facts, then, if n quantities are to be lefined, at least n 'units' are necessary. If it means choice made by assigning a value to some arbitrarily onstructed body or system, then no 'unit' is necessary as Planck's 'natural' system shows), and the number ›f 'units' that is convenient is a matter of opinion. An 'absolute system', if it means anything, means ›ne in which arbitrary choices are made so as to make equal to unity all universal constants that have no theoretical significance. The suggestion to make many of the n arbitrary choices in this way is very valuable; but it does not impose a unique set of choices. In particular, it does not force us to make either three or four arbitrary choices in a manner different from the remainder.

Two main errors are responsible for a failure to accept these certain conclusions. One is the ignoring of the distinction between what I have called A and B magnitudes, and of the fact that many magnitudes can be both A and B. The other is the belief, fostered by mathematicians, that experiment can establish the *equality* of magnitudes of different kinds; every experimentalist knows that it can only establish their *proportionality*.

I am expressing no opinion whatever concerning the practical convenience of Prof. Giorgi's system. I am protesting only against the view, apparently entertained by himself and his followers, that the number 4 has any greater factual significance in connexion with the choice of 'units' than the number 3, which used to be favoured.

NORMAN R. CAMPBELL.

[1] NATURE, **136**, 71, July 13, 1935.

Points from Foregoing Letters

By means of their newly-devised supra-conducting galvanometer, Prof. E. F. Burton, F. G. A. Tarr and J. O. Wilhelm find that no thermo-electric current flows in a lead-tin couple if both junctions are kept below 3·7° K., when the metals are in the supra-conducting state.

The relation between the mass of the atomic nuclei of carbon and beryllium and the binding energy of their constituent alpha particles has been derived by Drs. H. S. W. Massey and C. B. O. Mohr.

The energy of the hardest known gamma rays (2·6 million electron-volts) obtained from ThC″ and supposedly from RaC can be related, Prof. G. J. Sizoo states, to the position of radioactive elements of odd charge, grouped according to their disintegration constants, plotted against the highest energy of the electrons (beta rays) they emit. The graphs show a simple relation between the two quantities in the case of elements of even and of odd charge number, and suggest that the hard gamma rays now ascribed to RaC may really be due to RaC″ and that similar radiation may be expected from UX_2 and AcC″.

New X-ray and electron-diffraction analyses of carbon tetrachloride vapour have been made by Messrs. Ch. Degard, J. Piérard and W. v. d. Grinten. Both methods give values for the interatomic distances in good agreement with recent electron-diffraction investigations. From microphotometer records of electron-diffraction photographs, the influence of thermal vibrations could be detected.

Drs. G. S. Carter and L. W. Mapson find that various sterols have an action similar to that of acetylcholine, weakening and slowing the beat of the frog's heart, but they nevertheless appear to balance one another's effects when present together. The addition of either a sterol or acetylcholine to the gastrocnemius muscle of a frog in the resting winter condition leads to prolonged contraction, but when added together, only a normal twitch is observed.

From the amount of vitamin C (ascorbic acid) extracted from a potato under various conditions, M. van Eekelen concludes that vegetables contain a ferment which partially oxidises the ascorbic acid and interferes with its titration. This effect may be eliminated by the addition of 3 per cent trichloracetic acid. The apparent increase in ascorbic acid observed by McHenry and Graham was due, according to Van Eekelen, to the destruction of the interfering oxidases and not to the liberation of more ascorbic acid from an ester.

E. J. W. Barrington reports the occurrence in the intestine and skin of the ammocœte larva of the brook-lamprey of a proteolytic enzyme apparently similar to that already known to exist in the ascidians. The alimentary systems of these forms are thus physiologically more closely akin than had been suggested by early work on the same subject.

Prof. E. C. C. Baly considers theoretically the velocity of activated chemical reactions brought about in two stages, such as those occurring in biological changes where an enzyme is adsorbed on a co-enzyme.

Drs. G. B. B. M. Sutherland and W. G. Penney point out difficulties in reconciliating the shape of the NO_2 molecule inferred from a study of the force fields of triatomic molecules with that deduced from the absorption of infra-red light, and suggest a re-examination of the contours of the absorption bands of NO_2.

Certain viscous materials like golden syrup run out continuously from an orifice while others like clay paste drop out in 'blobs'. Dr. R. K. Schofield and G. W. Scott Blair ascribe the difference to the rate of variation in viscosity with shearing stress, and direct attention to the importance of this factor in such practical matters as the 'shortness' of flour dough and the 'necking' and rupture of metal cylinders.

Research Items

Excavations at Tepe Gawra, Iraq

THE elimination of all but three archæological expeditions to Iraq through the working of the Antiquities Law would add interest to almost any find in the season which has just passed; but the excavations which have been carried out by the joint expedition of the Museum of the University of Pennsylvania and the American School of Oriental Research at Tepe Gawra are in themselves of too great importance to need extraneous enhancement. Mr. Charles Bache, field director, in a report circulated by Science Service, Washington, D.C., states that he has now reached the level of the twelfth city (counting from above) on the site. This he dates at about 4000 B.C. Exploratory trenches have revealed the existence of eight earlier levels. In the recently discovered twelfth city, which appears to have been destroyed by fire, no trace of metal was found, and it is concluded that the inhabitants were still in the neolithic stage. Its architecture is superior to that of the three cities immediately following. The pottery here, as well as in the eight succeeding, later levels, is of the 'painted' type. In a large building which has just been uncovered, the largest of the many rooms measures 37 ft. × 17 ft., a remarkable feature being that its mud-brick walls are coated with a fine white plaster. This is the earliest use of white plaster that has been discovered hitherto, and indicates knowledge of the process of burning lime. The fact that the walls of the room appear to be oriented to the cardinal points suggests a knowledge of astronomy. While no flat seals have been found, two impressions indicate their use.

Sex and Cultural Status

DR. J. D. UNWIN, in an address delivered to the Medical Section of the British Psychological Society in March last ("Sexual Regulations and Cultural Behaviour". Oxford University Press. Pp. 63. 2*s*. 6*d*. net), restates the argument for his view that opportunity for the satisfaction of the sexual impulse is related to the type or grade of culture of a society. Societies are classified according to their behaviour in relation to their objects of worship: 'deistic', when temples are erected to a god; 'manistic', when there are no temples, but acts of worship are performed at the graves of the powerful dead; and 'zooistic' when in times of difficulty offerings are placed before a "strange power". Each of these types of society has a characteristic form of sexual opportunity. Societies permitting pre-nuptial freedom are zooistic; those inflicting an occasional continence are manistic; while those insisting on a complete pre-nuptial continence are deistic. An analysis of social conditions on these lines indicates that there is a relation between sexual energy and social energy, the latter being a manifestation of certain inherent powers which remain potential except under conditions of continence. They are then released and the society becomes 'expansive'. In the past, sexual opportunity has been reduced to a minimum only with the introduction of absolute monogamy; and in human records there is no case of an absolutely monogamous society which has failed to display great energy. On the other hand, if the condition of absolute monogamy is relaxed, as usually has happened, the society loses its energy and power of expansion and passes from one grade to another, as happened in the Christian church, when, the regulations of continence being relaxed, it ceased to be purely deistic, and passed to the manistic stage with the introduction of the medieval cult of the saint.

Application of Vocational Guidance Methods

REPORT No. 6 of the National Institute of Industrial Psychology presents the results and methods of "A Vocational Guidance Research in Fife" carried out by F. M. Earle and J. Kilgour. The inquiry was designed to give comparisons between children in different stages of growth, by testing the same children at intervals with the same tests; to differentiate between children of urban and rural areas; to study the question of the best age at which vocational guidance studies should be begun; and to determine minimum standards of qualities of abilities and temperament desirable for various occupations. The investigation showed the town children to be superior in verbal ability, and the country children to be superior in non-verbal processes and practical activities. Interesting results concerning the consistency of test-scores from year to year are presented. Those of general intelligence show the highest consistency, but the tests of English and arithmetic gave comparable scores after a one-year interval, but not longer. In the case of mechanical ability the results suggested that it was of relatively late development, and could be measured more accurately between the ages of twelve and fourteen years than between ten and twelve years. Measures of mechanical ability were applicable at all ages, but reliable for short periods only. In view of these conclusions, the report recommends that there should be two stages in the application of vocational guidance methods; at the first the child should be tested before the age of twelve years with regard to recommendations for specialisation in later school work, and at the second stage, between the ages of twelve and fourteen years, he should be tested with regard to vocational recommendations.

Results of the Vernay-Lang Kalahari Expedition

THE freshwater fishes and the reptilia and amphibia are reported on by Henry W. Fowler and V. Fitzsimons respectively in vol. 16, pt. 2, of the *Annals of the Transvaal Museum* (Scientific Results of the Vernay-Lang Kalahari Expedition, March to September, 1930), February 1935. The fishes are very interesting, most of them showing a large range of variation, especially in colour. 900 specimens were secured, representing thirty species, of which twelve are new. The fishes from the Tsotsoroga Pan and from the Nata River are probably the first ever collected in these localities, those from the first having come originally from the Okovango inundations, the Nata River rising independently in Southern Rhodesia and running directly into Makarikari Lake, which is strongly brackish. Some of the fishes survive even in the larger brackish pools. The reptilia and

aphibia are not confined to the Kalahari, but in- ıde specimens from Bechuanaland Protectorate, ransvaal and Southern Rhodesia. They form a rge collection of 1,452 specimens, belonging to 23 milies and sub-families, 60 genera and 99 species ıd sub-species : tortoises and turtles, one crocodile, ;ards, chameleons, snakes, frogs and toads. 18 ew species and sub-species are fully described, eliminary diagnoses having been published already / the author. These include a *Kiniscys* and a *elusos*, a *Typhlops*, a *Chlorophis*, a *Psammophis* and *Xenocalamus*, with several Lacertilia and Amphibia. aluable field data are given, including breeding ɔtes in many cases.

ife-History of a Nematode in Mice

B. SCHWARTZ and J. E. Alicata (*J. Wash. Acad. ci.*, 25 ; 1935) describe the life-history of *Longi- riata musculi*, a nematode parasitic in mice. The ggs hatch in about twenty-four hours after passing om the host, and the larvæ undergo one moult and e then infective to mice ; these larvæ correspond ı morphology and behaviour to third-stage larvæ f trichostrongyles in general. White mice were ıfected by the larvæ by way of the mouth and ırough the skin, and each portal of entry resulted ı the worms reaching the small intestine, where ıey underwent their entire development, including vo moults. The route from the skin to the intestine as not been ascertained ; passage through the lungs 'as exceptional. In three white mice infected ırough the skin, egg-production by the worms was mited to about two weeks. Infection of two mice y way of the mouth resulted in a much greater utput of eggs by the worms, which persisted as long s the mice survived, 32 and 63 days respectively, fter the infection. It is suggested that the striking ifference in egg-production by the worms in these wo groups is probably due to a marked stimulation f the defence mechanism of the host coincident with he migration of the larvæ following infection through he skin. This stimulation is either lacking or not ıarked when the larvæ enter by way of the mouth.

tructure of *Drosophila*

THE fly *Drosophila melanogaster* has become one f the most widely used laboratory animals for enetical and other studies. The general structure f the creature, as distinct from the group of Diptera o which it belongs, has attracted comparatively ittle attention. This gap in the knowledge of *Droso- ɔhila* has been met to some extent by a recent ublication by Mr. Eduard H. Strasburger. In a 60-page brochure, entitled "Drosophila melanogaster, Meig. Eine Einführung in den Bau und der Ent- vicklung" (Berlin : Julius Springer, 1935. 6.90 gold narks), he describes the general external and internal ınatomy of the insect in its larval, pupal and adult ɔhases, together with an account of metamorphosis ınd a very brief statement on the embryology. The vork is illustrated by 71 text-figures and is accom- ɔanied by a short bibliography. It should prove ıseful as an introduction to its subject, especially to vorkers who are not specialists in entomology.

Sooty Mould Fungi

MISS LILIAN FRASER has made a study of the fungi causing sooty moulds (*Proc. Linn. Soc. New South Wales*, 58, Parts 5–6, 1933 ; 59, Parts 3 and 4, 1934). Sooty moulds are caused by several fungi, which together produce a dark brown or black felt of mycelium upon the leaves and branches of certain plants following attack by aphids. Miss Fraser's first paper shows that the fungi all belong to three groups—the Capnodiaceæ, Atichiaceæ, and Fungi Imperfecti. After a review of the species of sooty mould occurring in New South Wales, it became obvious that two main types appeared—annual and perennial. The former were constituted largely from mixtures of *Dematium*, *Cladosporium*, *Alternaria*, *Asbolisia* and *Triposporium*, whilst perennial moulds incorporated members of the Capnodiaceæ, *Atichia*, and a species from the Fungi Imperfecti. The second paper records a large number of results from cultural experiments with all types of sooty mould fungi. They are all shown to require different optimum concentrations of specific carbohydrates and nitrogen, and this fact may explain their distribution on plants attacked by woolly aphis or greenfly. 'Honey-dew' secreted by these insects consists of dextrin and other specific complex carbohydrates, along with protein material.

Chinese Loess Deposits

Observations by Prof. G. B. Barbour on the loess of North China (*Geograph. J.*, July 1935) clear up some points in regard to the nature and origin of the Chinese loess. The term loess has been employed to embrace three types of surface deposit. Loess accumulated during the Malan (Upper Pleistocene) stage of aggradation, which is generally unbedded, over much of the North China highlands rests on an older deposit having certain distinctive features. This deposit is more clayey and has a crude layer structure. The thick layers are more loessic in character, darker in colour and very like the upper Malan loess. It would appear that these layers represent a succession of soil horizons from which the soluble material was leached, and the arrangement suggests that deposition was interrupted by long intervals during which the surface was exposed to weathering. This series of deposits Prof. Barbour terms banded loessic loams. Still older is a series of red clays referred to the Pontian stage of the early Pliocene. These are associated with a less rugged topography than that of to-day. Chemical and mechanical analyses of the material showed that the æolian process was dominant in the deposition of the Malan loess and the banded loams. Prof. Barbour goes on to try to correlate these deposits with climatic changes. The general conclusions point to warm semi-arid conditions in the lower Pliocene, with increase of rainfall in the middle of the period and cooler and drier conditions at its close. At the end of the lower Pleistocene, a milder and damper climate (Choukoutien stage) was followed by the cold semi-arid Malan stage, which gave way to present conditions at the close of the Pleistocene.

Weather Cycles and Droughts

IN a paper read before the American Meteorological Society in June, Mr. Halbert P. Gillette attributes the recent severe drought in the United States to the coincidence of the minima of several long cycles of rainfall. The most marked of these is about 152 years in length, with an amplitude of 25 per cent ; he finds this cycle not only in New England rainfall but also in the Nile floods, the tree rings of pine and *Sequoia* in Arizona and California, and the annual 'varves' or clay laminæ deposited during the

retreat of the last ice sheet in Canada. He considers that this cycle also determined the succession of halts and rapid retreats of the ice sheet in Finland. Judging by the evidence presented, the cycle of 152 years is probably real, and is important in geophysical phenomena; but the method of periodogram analysis adopted is not mathematically rigid, and the shorter cycles tabulated rarely agree with those found in meteorological data by more exact methods. A novel point is that each cycle is supposed to go through a 'cycle of amplitude' of many times its own length, that of the 152 year cycle being estimated as 1,825 years, but for the shorter cycles at least this apparently represents merely the 'beat' with the annual cycle.

A Recording Manometer

PAPER No. 91 published by the Safety in Mines Research Board is entitled "A Recording Manometer having Low Inertia", by G. Allsop and H. Lloyd. The principle of this manometer is the use of a thermionic valve connected to an oscillograph, which records the displacement of a small diaphragm exposed to transient pressures such as are produced by explosions. Various improvements on the original type are described, and it is shown that this manometer, with small variations, can also be used as a dynamometer. The appliance appears to be quite satisfactory, but is tolerably expensive, and is not likely to replace ordinary manometers for everyday work in mines, in which explosion pressures do not have to be measured. For measuring such transient pressures, especially where the cost of an appliance does not enter into the question, this ingenious manometer appears to be quite satisfactory.

Kiln-drying of Wood with Ozonised Air

THIS problem has recently been discussed by S. N. Kapur (*Indian For. Rec.*, **20**, Pt. 13. Delhi: Manager of Publications, 1935). The method consists in drying wood in an atmosphere containing small quantities of ozone, and is based on the assumption that the constituents of the wood during the long periods required for air-seasoning are subject to slow oxidative changes, which transform the sap contents chiefly—and according to some authorities the wood substance as well—into more stable compounds, thereby making the wood less liable to shrink and swell with changes in the humidity of the surrounding atmosphere, and consequently, more suitable for high-quality work. In summing up the results of his investigations, the author says that woods containing oils and oleoresins, which are difficult to 'kiln-dry', are in no way benefited by the addition of ozone to the circulating air in the kiln; that the addition of ozone to the air in the kiln does not accelerate the rate of drying of either resinous or non-resinous woods; and that timbers dried in an atmosphere of ozone, that is, 'artificially aged', do not show any greater stability towards changes of atmospheric humidity than those dried in a kiln without the addition of ozone.

Structure of Platinum Compounds

THE structure proposed for platinous compounds of the 4-covalent type [Pt a_2b_2] by Werner was that the valencies have a planar arrangement. A test of this, and a differentiation between a planar and a tetrahedral arrangement of valencies, is provided by substitution derivatives of bisethylenediaminoplatinous salts, [en_2 Pt] X_2. Diphenyldimethyl derivatives have been prepared by W. H. Mills and T. H. H. Quibell (*J. Chem. Soc.*, 839; 1935), and the optical activity of the compounds leaves little doubt that the planar configuration proposed by Werner is the correct one. The salts investigated proved capable of resolution into antimeric optically active forms showing a high degree of optical stability. The regular tetrahedral arrangement of valencies is excluded, and there are no reasons for inferring a pyramidal rather than the more symmetrical planar configuration. The planar arrangement of the platinum valencies with the intervalency angle of 90° is also shown to give rise to a practically strainless ring, whilst an arrangement with a tetrahedral valency angle would give rise to a very considerable strain in a 5-atom ring composed of carbon and nitrogen atoms and one 4-covalent platinum atom.

Einstein's Gravitational Equations

WE have received a very brief letter on this subject, dated June 2, from Prof. J. Ghosh; to make it intelligible to a wider range of readers it seems advisable to incorporate it with some references to Einstein's own work. The gravitational equations originally proposed, namely,

$$R_{im} - \tfrac{1}{2}g_{im}R = -8\pi T_{im},$$

represented a law of conservation such as that of momentum or mass and energy. Moreover, the left-hand side of the equation arose naturally in at least two mathematical processes. In spite of this, Einstein later (*Math. Ann.*, **97**, 99; 1927) gave electromagnetic and cosmological reasons for suggesting that the coefficient $\frac{1}{2}$ should be replaced by $\frac{1}{4}$. Prof. Ghosh (*Z. Phys.*, **85**, 511; 1933; and **94**, 411; 1935) has investigated the solutions of the new equation in four cases, corresponding to empty space, a single particle, an electron, and a rather more general system with radial symmetry. The results all contain a term belonging to de Sitter's world. Thus the new field equations automatically involve the cosmological constant, which is usually introduced as a special hypothesis. It is desirable that Prof. Ghosh's work should be extended to a more general distribution of masses, but this appears to be difficult.

Changes in the Spectrum of γ Cassiopeiæ

THE spectrum of γ Cassiopeiæ contains hydrogen lines each made up of double emission lines superimposed on a broad absorption line. Unlike many such stars, the spectrum had been considered to be always the same until recent observations by Dr. W. J. S. Lockyer showed that the two components of each of the double emission lines went through regular changes of relative intensity. This brought the star into line with other bright hydrogen line stars, most of which show similar changes. Later observations described by Dr. Lockyer (*Mon. Not. R.A.S.*, **95**, 520), however, show a most unusual type of change in these lines. The red component of each double had faded right out in March 1934, after which the remaining single emission lines (at that time forming the violet components) moved across to the position of red components, and in November new faint violet components appeared, the lines being again double, but with strong red and faint violet components. Such a change is believed to be unique in the history of such stars, and is difficult to explain by any of the current hypotheses.

Native Iron from West Greenland

By Sir Harold Carpenter, F.R.S.

THE structure and constitution of the native iron of Ovifak, Disco Island, West Greenland, have been the subject of controversy in the past, and in particular, uncertainty exists as to whether it does or does not possess the Widmanstätten structure which is characteristic of meteoric iron. By the kindness of Dr. L. J. Spencer, I have recently been enabled to investigate a sample which is contained in the collection of minerals in the Natural History Museum.

The iron was found to be friable and somewhat oxidised. When crushed, it was seen to consist of grains of metallic matter which were apparently cemented together by basalt and oxidised material. As it was impossible to drill a sample, a piece of it was ground in a percussion mortar and after screening the powder the metallic matter was separated from the residue with a magnet and then analysed. The sample thus obtained was contaminated with a little oxidised material, but the results shown in the first line of the table below give a good approximation to the composition of the metal.

	Fe	Ni	C	Co	Cu	SiO_2	CO_2
Ovifak iron	93·9	2·50	1·63	0·98	0·21	0·24	nil
Mellor's analysis	95·15	2·55	3·11	0·93	0·48	4·18	
Meteoric iron	90·85	8·52	0·03	0·59	0·02		

The figures in the second line of the table represent the maximum percentage of the different elements reported in the analyses of the iron which have been carried out by numerous analysts (cf. Mellor, "Inorganic and Theoretical Chemistry", vol. 12, p. 522) while the figures in the third line represent the average of 318 analyses of meteoric iron calculated by O. C. Farrington (Mellor, p. 525). It will be seen that the carbon content of the Ovifak iron is greatly in excess of that found in meteoric iron, while its nickel content is considerably lower—in fact the maximum nickel content of this iron, namely, 2·55 per cent, is well below the minimum for meteoric iron, which according to Mellor is about 5 per cent.

A small piece broken from the sample was ground and polished for microscopic examination. When etched with 1 per cent nitric acid in alcohol, the structure was found to consist mainly of a massive white constituent in a finely divided duplex matrix, in which there were thin needles and bars which appeared to be of the same material as the white constituent (Fig. 1). Here and there in the specimen irregular white patches occurred, scattered through which were small particles that appeared to be of the same phase as the needles (Figs. 2 and 3). At high magnification the duplex constituent was resolved into a globular type of eutectoid structure (Fig. 4). When the specimen was etched with a

FIG. 1. × 75

FIG. 3. × 75

FIG. 2. × 75

FIG. 5. × 75

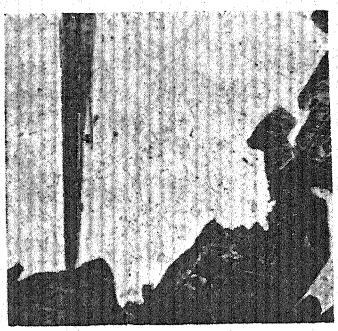

FIG. 6. × 75

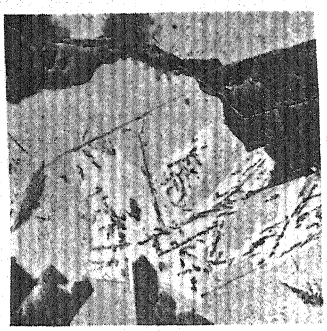

FIG. 4. × 750

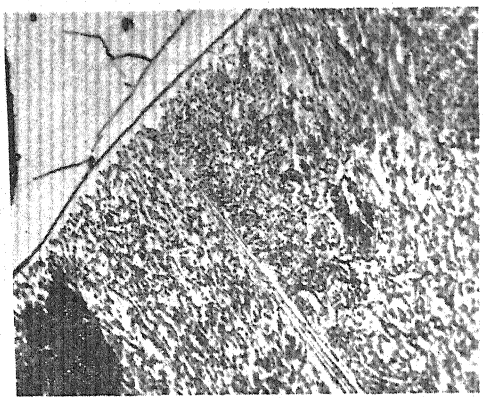

boiling solution of alkaline sodium picrate, the massive white constituent and the needles and bars were stained brown, thus proving them to be cementite (cf. Figs. 5 and 6, which represent the same areas as Figs. 1 and 3). The duplex matrix was very lightly etched, which is consistent with the view that it is the eutectoid of ferrite and cementite, and the irregular white patches appeared to be segregated areas of this mixture. Constitutionally, therefore, this 'iron' is a high-carbon nickel-cobalt steel.

The microstructure of the metal is altogether different from what would be found in an alloy of this composition which had solidified from the liquid state, and the question arises as to how it has been formed. The following view is accordingly put forward. The metal, which may originally have been carbonless, has been heated to a temperature probably in the neighbourhood of 900° C. in contact with carbon or more likely with carbon monoxide. This gas may have been produced by the combustion of lignite, beds of which occur on the island. Indeed it is possible that the metal has been produced from iron oxide which was first reduced by the gas to metallic iron and then carburised. The crystalline masses of cementite were formed in this way, but before the whole of the iron had been converted into the carbide, the temperature began to fall and the supply of carbon monoxide probably ceased, perhaps because of the exhaustion of the source of carbonaceous matter. At this point the alloy consisted of crystalline cementite and gamma iron saturated with carbon, that is, austenite containing more than 1 per cent carbon in solid solution. As the temperature fell, needles and bars of proeutectoid cementite crystallised from the austenite until the eutectoid temperature was reached, when the remaining austenite changed to the finely divided globular type of pearlite seen in the micrographs. The segregated areas may have been produced by slow coalescence of the cementite in the eutectoid during geological ages.

I wish to acknowledge the assistance of Mr. C. W. Dannatt and Dr. M. S. Fisher in this work.

Economics of Air Transport*

THE report on the Economics of Air Transport in Europe, recently submitted by M. Henri Bouchée to the special sub-committee of the Air Transport Co-operation Committee of the League of Nations, appointed to study the constitution and operation of a main network of permanent air routes, affords a dismal picture of the frustration of science. The report shows clearly that such free competition as exists in Europe to-day is chiefly competition in paying out subsidies. The waste and inefficiency in aviation which result from this commercial aviation are difficult to parallel. In the three years 1930–32, subsidies for aviation cost the European taxpayer about 2,000 million francs. Even in 1933, only four companies in Europe had advanced even half-way towards paying their way. At the end of 1932 British enterprises were nearly two thirds of the way, German enterprises only two fifths, French enterprises one fifth, Italian enterprises one fifteenth and air transport in Europe as a whole nearly one third.

In regard to actual use made of different air routes, the figures given in the report show the startling supremacy of the London-Paris air route, which in 1932 carried 5274 t. km. per km. of line, its nearest rivals being the Amsterdam-London route with 744 ton km. and the Paris-Amsterdam with 623 t. km. On certain routes, such as the Venice-Brindisi route, the figures are as low as 21 t. km., while financial returns indicate even more strikingly the supremacy of the London-Paris route, which shows more tonnes-kilometres utilised than the whole of the Belgian, Swiss, Czechoslovak, Polish, Swedish, Danish, Finnish, Austrian, Hungarian, Yugoslav and Roumanian services put together.

M. Bouchée points out that if the aircraft of Great Britain and of Finland carried a complete load, they would no longer need a subsidy, while the aircraft of the Netherlands would be independent if they were loaded to 75 per cent of their capacity. These figures prove that, from an economic point of view, certain lines are already operated very efficiently, and indicate that unsubsidised air transport in Europe is a matter of efficient technique and sound organisation. The obstacles to co-operation and efficiency are mainly political, and the relatively short distances flown in Europe will illustrate this point. They do not afford the decisive advantage which is possible in long-distance flights, and the system, as M. Bouchée remarks, is far more of the nature of propaganda than economic utility or the fulfilment of permanent needs. While surface traffic does not provide fast transport in Europe, the area is suitable for fast day-time flying, and that part of it which is most economically active will soon be a single territorial district which a fast aircraft will cross in half a day's day-time flying. The present services do little to meet the need for fast transport. Equally important is the question of giving air transport the freedom which is natural to it.

M. Bouchée calculates that, by rationalisation of European aviation, the whole of the present traffic could be carried with a quarter of the present European air fleet. Redundant or grossly uneconomic lines could be closed down and others at present non-existent could be set up. Air transport in Europe needs to be considered as a public utility service in the same way as the Postal Union or the International Sleeping Car Company, and the realities of the situation faced, so that aircraft no longer follow routes imposed on them or keep to Customs airports, 'corridors of approach' or 'prohibited zones'. The question, M. Bouchée concludes, is a political one. It cannot be solved merely by experts. Some form of internationalism is necessary if the present subsidies in Europe are to multiply direct and fast air services across territory better equipped and more freely accessible. In itself, the close co-operation essential might make a decisive contribution to the moral unity of Europe.

* Economics of Air Transport. By Henri Bouchée. Air Transport Co-operation Committee, League of Nations. (London: George Allen and Unwin Ltd., 1935).

International Conference on Folk Dancing

THE conference on folk dancing which formed part of the proceedings of the International (European) Folk Dance Festival, held in London on July 15–20 under the auspices of the English Folk Dance Society and the British National Committee on Folk Arts, met at Cecil Sharp House, Regent's Park, London, under the chairmanship of Prof. John L. Myres. One session was held at the Phœnix Theatre, Charing Cross Road, for the exhibition of cinematograph films and lantern slides illustrating the Morris and kindred dances and Dutch traditional dances.

The communications submitted to the conference numbered fifteen. It was thus possible, by adhering more or less closely to a fixed time-table, to allow ample opportunity for discussion and illustration by dance displays. The majority of the papers were concerned with the description of specific forms of national or regional dances; one by Mr. Rodney Gallop dealt with the principles and methods of recording folk dances, and the remainder discussed on broader lines questions of interpretation arising out of the comparative study of the dance as a popular mode of emotional and æsthetic expression among European peoples.

Of the communications of a more general character, that with which the conference opened, by Dr. Elise van der Ven Ten (Netherlands), on some aspects of the folk dance in various stages of the development of folk art, with the discussion which followed, was of importance for its clear-cut formulation of the relation between the scientific study of the folk dance and the revival of folk dancing as a means of individual, social and national expression. The author classified the folk dances of Europe according to the place they now fill in the life of the people, pointing out that while in eastern Europe they are still a living form of art, in central Europe they are dying, or even, as in modern Germany, have virtually become extinct; but in north-western Europe they are a revived art, largely owing to the work of Cecil Sharp (of which an account was given by Mr. Douglas Kennedy, director of the English Folk Dance Society, at a later stage of the conference).

It was laid down as a definite principle by Dr. van der Ven Ten and also by speakers in the discussion which followed the paper, that scientific study of the forms of the dance and its significance in the life of the folk is an essential condition of successful revival. Both in Germany and in Sweden, it was pointed out, such study had been found the essential preliminary in the revival of forms of the dance which would give full play to the development of individual and national consciousness.

Dr. Curt Sachs (Paris), in dealing with the symbolism of the dance, also stressed the importance in folk dance revival of study of the meaning or purpose of the primitive dance, which survives in the folk dance, although forgotten. The primitive dance, not being entirely æsthetic in origin, is on one hand a response to an internal physiological and psychological urge which raises the performer to an ecstatic magical plane, while externally its forms and associations with material symbols, such as the garland and the bridge, by mimicry or representation lead symbolically to a culmination in the promotion of fertility.

Among communications dealing with national or regional forms of the dance, such as that, for example, by Mlle. Louise Witzig (Zurich) on the Swiss folk dance and its significance in the revival of rural culture, and Prof. Césara Ehrenkreutz-Jedrzejewiczkowa on Polish wedding customs, reference was made to the reciprocal borrowing between court and peasantry. Such borrowing was also shown by Miss Violet Alford to have affected the character of the Morris dance. In her study of the Morris and the Morisca, she argued that before the Morris was affected by the fashion for the Moors, which was responsible for the dancers' black faces, and before the name 'Morisca', or 'Morris', was applied to it, it had once belonged to a pre-Christian European group of dances which were connected with a sacred animal.

An alternative view of the origin of the sword and stick dances, to which Miss Alford had referred, was put forward by Dr. Richard Wolfram (Vienna), who, elaborating from extended observation, especially in South Germany, a theory propounded four years ago, argued that these and associated 'chain dances' are a dramatisation of an initiation ceremony. He relied largely on the evidence of the association of such dances with secret societies; but, in the discussion which followed, reluctance was shown to accept his views as an exclusive or generally applicable interpretation, while a further obstacle to acceptance was the fact that there is no evidence in initiatory rites of the seasonal element inseparable from the sword and cognate dances.

Among the numerous points of interest which emerged from the communications of a more purely descriptive character, reference can be made here to one or two only—such, for example, as the relation between music, song and dance in Norway (Dr. O. M. Sandvik, Oslo), the primitive magic of the hobby horse of the Calušari of Rumania (Prof. R. Vuia, Cluj), and the taboos on partnership in the dance between certain individuals, varying with the stage of the proceedings, in the dances which accompany the wedding ceremonies of Poland, as described in the communication to which reference has been made above. A remarkable cycle of folk dances from Holland and the rites with which they are associated was shown in a cinematograph film by Dr. D. J. van der Ven. These ranged from children's processional customs to obsolescent dances now performed only by the older folk in keeping up the practices of their younger days, and to the living customs of the Harvest Home, or the midsummer bonfire and accompanying battle, or the remarkable and characteristic Dutch feat of 'flag waving', a combination of calisthenics and juggling, which on account of its associations with folk festivals, as well as its action, may well link up, as Dr. van der Ven maintains, with the fertility magic of the other peasant customs which he described.

South-Eastern Union of Scientific Societies

ANNUAL CONGRESS

THE fortieth annual congress of the South-Eastern Union of Scientific Societies was held at Bournemouth on June 26–29, under the presidency of Prof. A. C. Seward, Master of Downing College, Cambridge.

In his presidential address, Prof. Seward took as his subject "The Herbarium of the Rocks". He invited his audience to accompany him on a journey to a partially reconstructed forest of the Tertiary era. The Miocene Mascall flora of the John Day Basin of Oregon shows a close resemblance to that of the present-day Redwood Forest belt, although the former is many miles north of the latter. During the Oligocene period, Redwood forests very similar to those of California to-day have left traces in the Bridge Creek flora of the Crooked River Basin, south of the John Day Basin, and amongst other elements of this, for the most part dicotyledonous, flora is an Asiatic element showing relationship with Chinese plants. A similar flora to the Bridge Creek flora is found to have a wide range, since it occurs in Switzerland, Greenland, Siberia and Manchuria, but it is now confined to a narrow belt on the coast of California and Oregon. The Goschen flora of Upper Eocene times is another flora that differs widely from modern floras in corresponding latitudes. The view that these floras owe the members that they have in common to a southward migration of the parent plants from high northern latitudes has been confirmed in recent years. There must be a common origin for the similar living floras on both sides of the Pacific. Fifty-nine per cent of the genera of the Goschen flora are recorded from Cretaceous beds in the northern hemisphere where now is an arctic climate. Prof. Seward suggested that perhaps the Cretaceous ancestors of Tertiary plants were more tolerant of low temperatures. The ring of Tertiary floras that girdles the polar regions shows a decline of climate as compared with those of Cretaceous times. The Mull flora has much in common with that of arctic lands, and this with the other Tertiary flora represented by the inadequately-studied flora of Bournemouth show that there were then two distinct botanical provinces.

In the Archæological Section, Mr. T. D. Kendrick spoke on "Early Christian Art in the British Isles". Mr. J. B. Calkin demonstrated that prehistoric Bournemouth was full of interest. He has made a large collection of pottery and flint implements, which for want of a public museum are not available to the general public. His story of Bournemouth began with prehistoric man's implements found in the gravels between that town and Christchurch. Whilst there is no evidence of glacier conditions, the area was abnormally cold during parts of the Pleistocene era. Acheulean man lived here before the gravels were laid down, which were due to subsidence. At one time the area contained more than a hundred barrows. Few have been properly excavated, an exception being those of Hengistbury. Strangely enough, scarcely a single barrow faces Poole Harbour. Ten drinking beakers out of eighteen for the whole of Hampshire have been found in the district. Two food-vessels have come from Swanage, associated in each case with a human skull. In one Bronze Age site more than a hundred urns came to light, although most of them had been destroyed. An early Iron Age culture was found in Long Field, Hengistbury, corresponding with that of Hallstatt on the Continent. Mr. Calkin exhibited many of the remains to which he alluded in his paper.

Prof. R. J. Tabor and Prof. M. C. Potter read papers of a botanical nature. The Rev. F. C. R. Jourdain spoke on ornithological progress during the past fifty years, and commented on the new nomenclature that he and others were successful in bringing into effect, and on the increased study of bird-life as shown by the British Ornithologists' Union, now numbering more than 400 members, although it commenced in 1858 with twenty members. Some attention was given to the modern recognition of races of birds as well as species. "If the breeding ranges of two forms overlap or coincide and yet remain apart they must be species; if on the other hand they are obviously closely allied and yet replace one another geographically they are races." The hooded and carrion crows are distinguishable at a glance, and although they as a rule have different breeding ranges, there are places in Scotland, Germany and Russia where they interbreed. Mrs. K. Grant spoke on "Migration of Butterflies" and showed an exhibit from the entomological department at Rothamsted.

In the Geological Section, Dr. H. D. Thomas made out a good case for certain lines of evolution, or trends, in respect of fossil foraminifera and other lowly forms of life. A lecture by Lieut.-Colonel C. D. Drew on "Recent Excavations at Maiden Castle" was followed by a visit under his guidance by about seventy members to the earthworks. Here the cutting into the filled-up ditch, which had yielded neolithic evidence, was seen and also the remains of the Roman temple, round which were strewed innumerable roofing-tiles. Reference should be made to the small bronze bull which was found, with the upper parts of three human figures on its head and back; this was afterwards seen in the Dorchester Museum. In the museum was noticeable a large area covered with Roman tesselated pavement, laid down as originally on the floor of a Roman villa.

Dr. Vaughan Cornish gave one of his delightful talks on "Scenic Amenities in Town and Country".

Visits were made to Corfe, Littlesea, Beaulieu Abbey, Poole Pottery Works, Wareham, and other places of scientific interest, whilst on the social side of the Congress, the Mayor and Corporation gave the Union a civic reception at the Pavilion.

Educational Topics and Events

EDINBURGH.—Sir Charles Sherrington has been appointed Gifford lecturer for the years 1936–37 and 1937–38.

At the medical graduation ceremonial on July 17, the honorary degree of LL.D. was conferred on Prof. A. N. Richards, professor of pharmacology in the University of Pennsylvania.

LEEDS.—Mr. H. S. Clough has given £250 towards the erection of an observatory to house the telescope and other astronomical instruments recently presented by Mrs. Bolton of Bramley.

LONDON.—The following appointments have been made: Dr. James Whillis, since 1923 lecturer in anatomy at the College of Medicine, Newcastle-on-Tyne, to be reader in anatomy (Guy's Hospital Medical School) as from October 1; Dr. Jerzy Neyman, since 1927 lecturer in mathematical statistics at the Central College of Agriculture, Warsaw, and also since 1928 head of the Biometric Laboratory, Nencki Institute, Warsaw, to be reader in statistics (University College) as from October 1.

The title of professor of statistics in the University has been conferred on Dr. E. S. Pearson, in respect of the post held by him at University College.

The Sir George Jessel studentship in mathematics for 1935 has been awarded to Mr. A. E. Chapman, of University College.

Mr. E. P. Stibbe, senior demonstrator of anatomy at the London Hospital Medical College, has been appointed to the University readership in anatomy tenable at King's College from October 1.

PROF. A. NORMAN SHAW has been appointed head of the Physics Department and director of the Macdonald Physics Laboratories at McGill University, Montreal, in succession to Prof. A. S. Eve, who has retired.

A 'SABBATICAL YEAR' for university teachers is a notion that has obviously much to recommend it, but it has failed hitherto to gain effective acceptance in Great Britain as a feature of university policy. In a statement recently submitted on behalf of the Association of University Teachers to the University Grants Committee, it has been urged as a "highly desirable reform" and in an article by Mr. G. F. H. Harker, of University College, Cardiff, published in the April issue of the *Universities Review*, the case for it is argued with considerable force. The writer quotes Bertrand Russell's "Every university teacher ought to have one year in every seven to be spent in foreign universities . . ." and points to the spectacular rise of America to the front rank in so many fundamental branches of thought and action as attributable in some measure to American universities encouraging the members of their teaching staffs to do this very thing. English universities are more or less autonomous, and are proud of the fact, but they suffer, especially the smaller ones, from a correlative tendency to isolation. During vacations the average university teacher, except for spells of necessary relaxation, divides his time between private work for supplementing his income and the preparation of lecture courses for the ensuing session. Moreover, only a lengthy stay abroad, and that not during vacations, can give any real insight into universities in another country.

THE Tennessee Valley Authority has provided for the world an object lesson in the operation of a planned economy without recourse to compulsion. The salient features of this vast undertaking are already widely known in Great Britain thanks to the recent publication in *The Times* of special articles by Prof. Julian Huxley. An account of its more specifically educational aspects is given in *School Life* of March under the heading "A New Frontier in Education". The authority assumes towards its labour force responsibilities more like those of the head of a family than the mere cash nexus of the paymaster. It charges itself with the organisation of an environment suitable for a civilised life. In its various training programmes it has grappled successfully with the difficulties of providing ample facilities for instruction for employees without disorganising the work on which they are engaged. The normal working hours are 5½ hours a day for six days a week. For the more talented workers opportunity is provided for changing every five weeks from one to another of ten different types of work. The authority has created a civil service of its own in which appointments are, it is stated, made on the basis of merit only. This would-be Happy Valley covers 40,000 square miles and some six million people are or will be affected.

Science News a Century Ago

Death of Gilbert Thomas Burnett

ON July 27, 1835, at the early age of thirty-five years, Gilbert Thomas Burnett, the first professor of botany in King's College, London, died, worn out by "multiplied literary, lecturing and professional labours". The son of a London surgeon and born on April 15, 1800, Burnett began the study of medicine at fifteen years of age, and, after commencing practice as a surgeon, gave lectures on medical and general botany at the Great Windmill Street School of Medicine. He frequently lectured at the Royal Institution, gave a course at St. George's Hospital, and in 1831, on the opening of King's College, was appointed to the chair of botany. At the time of his death he was also professor of botany to the Apothecaries' Society. His "Outlines of Botany" in two volumes appeared shortly after his death, while a large series of "Illustrations of Useful Plants Employed in the Arts and Medicine", which was published during 1840–49 with drawings by his sister, contained text chiefly by Burnett himself.

J. D. Forbes in the Pyrenees

ANOTHER entry from the "Journal" of Forbes during his visit to the Pyrenees in 1835, dated July 29, said: "I left Luz on foot at half-past five, for Gavarnie. . . . Beyond Gèdre, where we breakfasted, I found in accordance with the accurate account of Charpentier, magnificent crystallised limestone in the granite: the granite here, like that of Héas, is altogether a strange rock, and often passes into a slaty structure, becoming gneiss, or mica slate, besides enclosing masses of these rocks, and forming an absolute breccia. But where crystalline, it seems to me never stratified; the fissures and the flat surfaces they leave can never be traced to any distance, and when they disappear, are as often at right angles to the former as not. The appearance of vertical stratification is often caused by the rain courses, as in the valley of the Reuss at St. Gothard, to some parts of which this valley has a great resemblance. . . ."

Berzelius in Paris

ON July 31, 1835, *The Times* announced that "The celebrated chymist M. de Berzelius has just arrived in Paris. He is accompanied by one of his former pupils M. Dahestraeno, professor of chymistry at Stockholm. It is the intention of these two *savans* to remain in Paris until the beginning of September, when they will set out for Germany, to be present at the meeting of the naturalists at Bonn."

Societies and Academies

PARIS

Academy of Sciences, June 12 (*C.R.*, 200, 1997–2044). HENRI DESLANDRES: A simple and general relation of the molecular spectrum to the electrons and rings of electrons of the constituent atoms. JEAN REY: The energy yield of thermo-compressors. The importance of its definition. DAVID WOLKOWITSCH: The conoid of Plücker. JEAN LERAY: The problems of conformal representation of Helmholtz: the theory of [ships'] wakes and bows. JEAN MARIANI: The general sign[illegible]cation of the macroscopic theory of fields. A. A. GUNTZ and E. BELTRAN: The influence of H^+ ions in the phenomena of reduction and hydrogenation. The view is put forward that the attraction of the H^+ ions and the electrostatic repulsion of the nuclei suggests that the H^+ ions present in certain media may possess the property of preactivating a large number of molecules producing catalysis and syntheses. MLLE. SUZANNE VEIL: Contact batteries and the effect of short-circuiting them. MARCEL SERVIGNE: Some phenomena of cathodic phosphorescence. Comparison of the cathodic phosphorescence of precipitated and natural calcium tungstate (scheelite), showing the effect of the crystalline state and of the addition of traces of silver on the phenomenon. LÉON and EUGÈNE BLOCH: Research on the regularities of the Cu III spectrum. MARTIN BATTEGAY and EUGÈNE RIESZ: The di-anthraquinonylguanidines. JOSEPH WIEMANN: The synthesis and constitution of a dimethylhexite. ANTONIN LANQUINE: The relations of the Saint-Maximin (Var) Trias with the south-eastern termination of the Sainte-Victoire chain and with the eastern termination of the Olympe chain. ROBERT PERRET and JACQUES BOURCART: The lavas of Adrar and Asger. JACQUES FROMAGET: The discovery of new evidence of the upper marine Trias in the Haut-Laos synclinal. MLLE. HÉLÈNE ARLAUD: The Turonian of the neighbourhood of Cassis and the Cretacean movements in western Provence. MARCEL CORMIER: Hydrocyanic acid in *Pyrocydonia Winkleri*. Similar to the parent quince tree, the hybrid *Pyrocydonia Winkleri* furnishes hydrocyanic acid, existing in the plant in the state of heteroside. The proportion of hydrocyanic acid is about seven times that found in the parent quince. HENRI COLIN and HENRI BELVAL: The glucides of flour and dough. BASILE LUYET: Nuclear structure studied *in vivo* by the method of ultra-violet photography. The resolving power of the microscope can be about doubled by using ultra-violet light with quartz objectives with glycerol immersion. Chromatin is specially opaque to the ultra-violet rays, contrasting with the cytoplasm, which is much more transparent. The author has applied these facts to the study of the physical structure of the caryoplasm. SERGE TCHAKHOTINE: The localised flocculation of colloids in the cell by ultra-violet micropuncture. LOUIS COTONI and JACQUES POCHON: A new method of titrating antipneumococcic sera by neutralisation of the antibodies *in vitro*. ALFRED BOQUET and ROGER LAPORTE: Bail's phenomenon and tuberculin intoxication.

CAPE TOWN

Royal Society of South Africa, April 17. M. R. LEVYNS: Veld-burning experiments at Oakdale, Riversdale. These experiments have extended over five years and have been carried out on rhenosterveld. The results after burning differ from those previously obtained at Stellenbosch. There an immediate return to rhenosterveld was demonstrated. In this case the vegetation undergoes a series of successional changes before rhenosterveld is once more established.

May 15. F. G. CAWSTON: A second intermediary host for trematodes. J. V. L. RENNIE: On the flora of a high mountain in South-West Africa. In the higher parts of the Auas Range, near Windhoek, the thorn-veld is replaced by small shrubs, several of which might be interpreted as relics of an older flora in South-West Africa. *Passerina* and *Stoebe plumesa* are recorded for the first time from that territory. It has generally been assumed that the presence of certain Cape genera in East Africa and Angola is due to migration in former times via the eastern side of the subcontinent. The species here recorded suggest that at least certain elements of the Cape Flora could have reached the Huilla Plateau in Angola via a western route. A. GALLOWAY: Some prehistoric skeletal remains from the Natal coast. J. L. B. SMITH: The "Galjoen" fishes of South Africa. The Galjoen fishes are placed in a genus of somewhat doubtful taxonomic position. Owing to a combination of characters the institution of a new family (*Dichistiidae*) is proposed. E. E. GALPIN and E. A. GALPIN: Some biological notes on *Boscia rehmanniana*, Pest., and *Olea verrucosa*, Link. W. E. ISAAC and B. GERSHILL: The organic matter content and carbon-nitrogen ratios of some semi-arid soils of the Cape Province. The average C : N ratio for these, namely, 10·6 : 1, is contrasted with that of the winter-rainfall area (15 : 1). Decreasing organic matter content is accompanied by a decreasing C : N ratio. Although the organic matter of the semi-arid type of soil is low, the percentage of nitrogen in the organic matter itself is higher than for the winter-rainfall series. Hydrogen ion concentration figures show that the semi-arid type of soil is the more alkaline of the two. I. DONEN: The effect of time of picking on the chemical changes of Kelsey and Gaviota plums in store (read on March 20). Time of picking has no marked effect on chemical changes in the Gaviota plums. First appearance of bladderiness in all samples was noticed after about 44 days in store at 34°–36° F. Coincident with this breakdown a complete reversal of the sugar equilibrium was observed in the last two pickings. In the first two pickings of Kelsey plums, rate of loss of sugar was initially high and then declined rapidly to a minimum. In the last two pickings it remained uniform throughout the observed storage life. Internal browning of the tissue, accompanied by a reversal of sugar equilibrium, occurred sooner in the early pickings than in the later ones. Acid loss was high when sugar consumption was low and it is suggested that increase in rate of loss of acid is an 'overdraft' on stored acid due to insufficient supply of acid from oxidation of sugars. Low nitrogen and low acid therefore favour good keeping quality. This is correlated with delay in time of picking.

CRACOW

Polish Academy of Science and Letters, April 1. C. BIALOBRZESKI and I. ADAMCZEWSKI: The application of dielectric liquids to the study of the 'bursts' of ionisation caused by the cosmic rays. Compressed gas in the ionisation chamber is replaced by a liquid, such as hexane. The phenomenon is more distinct and more frequent. M. CENTNERSZWER and

T. CHECINSKI: Thermal dissociation of silver nitrite. Dissociation of silver nitrite can be represented by the equation $2AgNO_2 \rightleftharpoons Ag + AgNO_3 + NO$. The constants of the Nernst equation have been determined. M. BLUMENTHAL and T. CHECINSKI: Kinetics of the thermal dissociation of silver nitrite. A. SKAPSKI: Enunciation of the law of mass action in systems of one or several phases, especially from the point of view of the equilibrium of reactions in metallurgy. M. HLASKO and A. SALIT: Measurement of the electrolytic conductivity of extremely dilute solutions. Measurements can be carried out by the authors' method at dilutions down to 10^{-7} normal. The values thus directly obtained differ only by 0·1–0·2 per cent from the values obtained by Kohlrausch's extrapolation formula. The apparatus used in such measurements must be constructed entirely of quartz. K. DZIEWONSKI, K. BERNAKIEWICZ and W. MALICKI: The reactions of thiourea with the arylalkylketones. M. KSIAZKIEWICZ: The zone of the external Carpathian klippes in the neighbourhood of Andrychow. (3) The stratigraphy of the klippes and their position in the tectonic of the western Carpathians. T. WISNIEWSKI: *Hydrilla verticillata* of the lacustral region of Suwalki (northern Poland). T. WISNIEWSKI and MLLE. L. GOETZEN: The structure of the lamellæ of the leaves in European species of the genus *Polytrichum*. B. PAWLOWSKI: The final climax association of the Alpine stage of the Tatras. ST. MARKOWSKI: The influence of changes of the medium on the development of the eggs of *Bothriocephalus scorpii*. M. RAMULT: The embryonic and larval development of the crustacean *Sacculina* in media of different osmotic conditions. K. PASSOWICZ: Researches on the behaviour of the daphnid *Daphnia pulex*, Geer, in liquids of different hydrogen ion concentration.

May 6. K. DZIEWONSKI and L. STERNBACH: New studies on the reactions of benzoyl chloride on the aromatic amines and on their products, compounds derived from quinazoline. J. NOWAK: Origin of the flint in the Pleistocene of Volhynie. M. KAMIENSKI: Remarks on the Trojaga andesites. W. FRIEDBERG: *Turritella scalaria* and some remarks on gasteropods with unfolded testa. W. SZAFER and BR. JARON: A lake of Pleistocene age in the neighbourhood of Jaslo. MLLE. A. KOZLOWSKA: Characteristics of the forest associations of the mountainous region of the Cieszyn district. ST. JASNOWSKI: Inheritance of some characters of the ear of wheat. F. GORSKI: Gaseous exchanges in some submerged aquatic plants in the course of assimilation. Study of the gaseous exchanges of *Elodea canadensis*. About 30 per cent of the oxygen escapes as bubbles, the remainder dissolving in the water. The bubbles contain 50–60 per cent of nitrogen and about 1·5 per cent of carbon dioxide. MLLE. IRÈNE REJMENT: Contributions to the knowledge of the Hepatic flora in the sub-Carpathian region near Cieszyn. JAN TRELA: The interglacial period at Samostrzelniki near Grodno from the point of view of the results of pollen analysis. J. ZACWILICHOWSKI: The innervation of the hooking organs in *Argulus foliaceus*. F. ROGOZINSKI and ZB. GLOWCZYNSKI: (1) The nutritive value of Canary grass seed (*Phalaris canariensis*). (2) Irradiation and growth. With animals submitted to a complete and well-balanced food regime, irradiation by ultra-violet light has no influence on growth, but if the diet is defective, the light exerts a very marked favourable effect. MME. B. KONOPACKA: Histochemical researches on the development of fish. Vitellogenesis in the gudgeon and carp.

Forthcoming Events

[*Meetings marked with an asterisk are open to the public.*]

Sunday, July 28

BRITISH MUSEUM (NATURAL HISTORY), at 3 and 4.30.—Miss M. H. Smith: "Plants".

THIRD INTERNATIONAL CONGRESS OF SOIL SCIENCE, July 30–August 7, to be held at Oxford. Sir John Russell: President.

Problems of Industrial Hygiene

THE annual reports of the director of the International Labour Organisation cover an extensive field, all the more because the boundaries between social and economic questions have been largely obliterated by the recent economic depression. Hitherto, the main work of the Organisation has lain in the field of protective labour legislation. In this field its activities have already been of direct concern to professional workers, whether in science or elsewhere ; and apart from the actual conventions already adopted by the International Labour Conference, a notable amount of research work has been carried out in subjects of direct interest to scientific workers, such, for example, as its studies on the operation of the radius clause, and the problem of the salaried inventor, industrial relations between staff and management, hours of work of professional workers, the status of engineers and chemists, and similar topics.

The extent to which an international labour code has been established has led to the suggestion that the goal of the legislative effort of the Organisation is in sight and that its remaining tasks are secondary. To the examination of this contention, Mr. H. B. Butler devotes a concluding chapter in his recent report (Geneva : International Labour Office, 1935) which is of particular interest to the scientific worker. At the outset, Mr. Butler rightly points out that social legislation is not static but dynamic. Already some of the conventions adopted are becoming out of date. Notably is this true of those bearing on questions of hours of work, in which the growing acceptance of the necessity for some further and wise distribution of employment or leisure is obviously a disturbing factor. Only as proposals are continuously put forward based on assiduous research can we hope to approximate to solutions of such problems which will offer the minimum of distress and the maximum satisfaction of man's needs. There are still important fields for scientific investigation which demand investigators of high quality. Such, for example, are the questions of training for industry, including vocational guidance, apprenticeship and technical education, and the many problems arising out of leisure and the provision of facilities for recreation which were discussed at an international conference at Brussels in June. Besides these, the special problems of the professional worker require fuller consideration, and the fields of industrial hygiene and safety offer an immense scope for future action.

Since the publication by the International Labour Office in 1928 of a report and a supplementary report giving a concise analysis of laws and regulations of all the great industrial countries, as well as a survey of the organisation and activities of safety associations in various countries, and the adoption at the Conference of June 1929 of a draft recommendation concerning the question of industrial accidents, the problems of industrial safety and hygiene have received a growing share of attention in Great Britain and elsewhere. Apart from the purely professional problems of the scientific worker, the work of the International Labour Organisation touches him at no point so closely as at this. Upon his co-operation the success of almost all its efforts in this field finally depends.

The prominence of these questions should not of course be wholly attributed to the influence of the International Labour Organisation. Quite

lependently, the Association of British Chemical anufacturers has already done a great deal to omote safety and hygiene in chemical industry r means of its model safety rules for chemical orks, its safety circulars with their particulars various accidents and their causes, its 'Safety ummary' of information on accidents and their evention. The annual reports of H.M. Chief spector of Factories record the way in which such atters are receiving increased attention in indus- y generally, and the success of the Industrial luseum at Horseferry Road, Westminster, and ie illustrated descriptions of industrial accidents sued quarterly by the Home Office, afford further vidence, if such be needed, of the widespread esire to make conditions in industry as safe and ealthy as possible.

Whether we approach the subject from the oint of view of the dissemination of information r of that of securing effective action, the part of he scientific worker is equally important. Both n the preparation of summaries or abstracts of afety information, or of such monographs as 'Occupation and Health", issued by the Inter- national Labour Office, and in their use, his par- ticipation is essential if the information provided is first to be accurate and then to be used effectively. There is still need for much wider use and more effective co-ordination of available information, so that experience gained in one firm or industry at the expense of human suffering may be freely available to prevent a similar occurrence else- where. Few industries are served so efficiently in this matter as the chemical industry, and the very circulation of such a publication as the *Journal of Industrial Hygiene* indicates the need for develop- ment in this respect.

Again, the participation of scientific workers in the publication of notes on accidents and hazards, their cause and prevention might well be more widely encouraged. Much valuable work is being carried out by various firms, but not all of this is published and made generally available. More- over, the whole field of industrial hygiene offers opportunities for research which are far from being fully explored. Much work of this type is pre-eminently suited for co-operative effort, and from this point of view the influence of the Inter- national Labour Organisation is highly important. While undoubtedly the actual investigations will best be carried out through national organisations, an international organisation can do much to delineate the problems and supply the stimulus where required, as well as secure co-ordination and avoid overlap.

Research work in industrial hygiene demands a high degree of co-operation between various classes of scientific and other professional workers. The annual reports of H.M. Chief Inspector of Factories afford continual evidence that failure to observe the provisions already laid down in the Factory Acts, and consequent industrial accidents, are due to the absence of skilled and qualified supervision, such as that of a chemist or engineer. Still more is it impossible to take adequate precautions and safety measures in the event of unforeseen con- tingencies, which can scarcely be entirely excluded from some processes or stages of development, in the absence of those who are able to bring a trained mind and expert knowledge to bear on any emergency.

There are welcome signs that this responsibility is now widely recognised among scientific workers, and that those occupying positions of responsibility are resolved to do all in their power to guard the worker in industry from risks of which he is often unaware and which only the scientific worker can appreciate. Certain professional organisations, such as the British Association of Chemists, have set themselves definite aims in this matter, and the Association of British Chemical Manu- facturers is already carrying out a large amount of valuable work. The proposals of the new Poison Rules in regard to the supervision of the manufacture of pharmaceutical preparations will certainly be closely scrutinised from this point of view.

There are, however, many industries where a great deal more remains to be done, where scientific and professional workers are isolated and few in number. To raise the standard of industrial hygiene and safety in such industries demands all the support which they can receive from their professional and scientific colleagues and from the investigations and general efforts of such organisa- tions as the International Labour Office. Only as the technical staffs are inspired by the conscious- ness of high professional traditions and solidarity in this matter of industrial safety, and as the work of the factory inspectors is continually reinforced by educational and research work stimulated by an international organisation pooling knowledge for the common benefit, can we hope to see the minimum standards of the law exchanged for those guaranteeing the maximum security of life and health.

Kenya: The Settler's Story

White Man's Country: Lord Delamere and the Making of Kenya
By Elspeth Huxley. Vol. 1: 1870–1914. Pp. xiii + 315 + 12 plates. Vol. 2: 1914–1931. Pp. vii + 333 + 12 plates. (London: Macmillan and Co., Ltd., 1935.) 2 vols., 25*s*. net.

THE author of this most interesting book is the daughter of a Kenya settler, reared and educated in Kenya. It is perhaps the most comprehensive account of the pioneer activities in farming and politics of European colonisation of those highlands in east equatorial Africa that has yet appeared. It is written round the life of that father of his adopted country, Lord Delamere, the ablest and most intelligent leader that the settlers have produced.

Kenya has, in the forty years of its history under British administration, been the centre of acute controversies, all of them raising issues that have reached far beyond its frontiers, affecting race relations and Imperial policy throughout the whole world. Kenya, owing to its geographical position, its unique climate, and the curious make-up of its very varied population, has always been, and will always remain, the focus, if not the storm centre, of a complex of difficult problems. It is not a normal land, and, like Ireland, it excites a romantic and even an emotional sentiment of intense affection, or intense antipathy, in all who have anything to do with it. That people 'fall in love' with Kenya is not surprising. The admirable photographs in this book will give some idea of the attraction of its spaciousness and beauty.

It has been said that Kenya is inhabited by the most difficult Europeans, the most difficult Indians, and the most difficult African natives in the Empire, all seeking livelihood in what is economically, and, from the point of view of the human species and his domestic animals, a most difficult country to harness to man's use. That the fair highlands of Kenya were so sparsely populated when less than forty years ago Europeans began, with official encouragement, to colonise it, was not due solely to the warlike proclivities of the nomadic Masai. Almost every known form of mycological, protozoan, helminthic and insect pest formed the flaming swords of death that guarded and still guard an apparent garden of Eden. Wheat rust, malaria, red water fever, rindepest, worm-infested herds of zebra, tsetse fly, and last but not least, swarms of locust of more than one variety contend with man for the domination of the land; and the fight is not won yet.

Lord Delamere was a romantic figure, part politician, part farmer and part Puck. Born in 1870, the only son of the second Lord Delamere, he was taken away from Eton at the age of sixteen, and, at seventeen, succeeded to the title and responsibilities of a feudal family estate in Cheshire. Civilisation, and the accidents of his birth and circumstances in England, for a young man of his temperament, were soon found to be constricting, and early he sought to escape from their toils. At the age of twenty-five he wandered through the port of Zeilah, that has recently become famous on account of the Italo-Abyssinian controversy, and through the semi-arid hinterland of Somali country into the country round Mount Kenya, and thereafter he devoted his remaining thirty-six years of life whole-heartedly to Kenya. His patrimony in England became but the milch cow from which the last possible drop was extracted for financing his very varied pioneer experiments in Kenya. Family, financial interest or motive, comfort, everything in life, he sacrificed on the altar of his passion for the colony.

By inheritance and upbringing, Lord Delamere was an eighteenth century aristocrat for whom there were three proper occupations—sport, agriculture and politics. But to inheritance and upbringing was added a personal individuality such as was possessed by the pioneer explorers of history, coupled with a very penetrating, if impish, intelligence, and a natural liking for and understanding of the African native, especially of the more primitive tribes. His personal handling of his favourite Masai in the troublous times of the War stands out as perhaps his most remarkable achievement.

Lord Delamere had inevitably an almost complete disregard of money and economics. He was recklessly generous and grandiose as regards the former. For himself, he lived hard and simply, but in his pioneer experiments in new agricultural introductions he was lavish, and the few successes had to compensate the bankers responsible for his overdrafts for many inevitable failures. The end of scientific experiment had to justify the means. Like many another English country gentleman who devotes his energy and substance to the tradition of agriculture, he always hoped but never really expected that the 'Home' farm would pay! Though Kenya owes a tremendous debt to Delamere for his farming experiments—

wheat, the introduction of Merino sheep, pedigree cattle, all of which he was the first to try out—it is not as an agriculturist but as a man of affairs that he made his greatest contribution.

Mrs. Huxley has given us on page 88 of the second volume the following admirable description:

"On many matters Delamere's advice was of great value to the Government. It was easier to deal with a man of his calibre than with eleven discordant elected members. He was willing to help as well as to harry. But he could be a dangerous opponent. He was always on the alert. Outwardly he was urbane, charming and courteous; ready, at any conference or interview, to voice an opinion in the most conciliatory, almost deprecating, fashion. But little escaped him; and at the first error of fact or flaw in argument he would pounce quickly, still with unruffled courtesy, his blue eyes twinkling as he puffed a large cigar, his head cocked on one side like a sparrow. On occasions he had a keen appreciation of the dramatic effect of sudden outbursts of temper, to be followed by a complete withdrawal and an apology so charmingly delivered that offence had to be forgotten."

This is an almost perfect picture of the man, whose sense of humour was never failing and whose mental resource was like a rapier. He did not suffer fools—especially official fools—gladly, and, like an African native he was a quick judge of both character and wits. Everyone official and unofficial knew that he was by ability and experience the outstanding figure in Kenya. Most people, especially his own native personal servants, loved him. A few people hated him.

Mrs. Huxley has written a faithful story of his adventurous life, and it needed to be told as she has told it. Of course, Delamere was the centre of all the storms and escapades of Kenya's eventful history. She has inevitably written of the controversies from the settlers' point of view. She is not always quite fair to the poor old Colonial Office, thousands of miles away in Downing Street. She is fully aware that the pro-Indian and pro-native enthusiasts have hitherto had most of the publicity, and she has fearlessly entered the lists. Her book is not always strictly impartial or objective, and doubtless it is the more stimulating and readable for that reason. Occasionally guilty of *suppressio veri*, she is very rarely, if ever, guilty of *suggestio falsi*. The book is remarkably free from any errors of fact—but, on page 224 of the second volume, Sir George Schuster, who had been financial adviser in the Sudan, was then financial adviser to the Colonial Office, and was later to become Finance Member of the Viceroy's Council, is wrongly described as an Indian Civil Servant.

The book contains all the essential quotations from official sources as to the origin and development of the official policy of European settlement, and from the all too numerous Commissions which have wrestled with constitutional problems in East Africa. It is cleverly and attractively written, and admirably produced. On page 83 of the first volume, Mrs. Huxley has penetrated very deep into the root causes of our Imperial difficulties over Kenya.

"This loss of faith is perhaps", she writes, "at the root of the misunderstanding and the bitterness that has grown up, since the war, between the settlers and their English rulers. For the colonists have in the main retained their old philosophy and preserved their faith. Economically they have believed, blindly like all producers, that the time will come when more raw materials will be needed. The intellectual isolation of colonial life has to a large extent cut them off from the influences which have brought about a change of philosophy in England. . . . To the gulf of distance, therefore, between the settler and the British voter who rules him, has been added a still deeper and more difficult gulf—the gulf of outlook. The colonist does not realise why the Englishman has apparently lost all sympathy with him. Inwardly he feels betrayed. The Englishman does not see that the colonist is guilty not of oppression but of consistency. So the settler stands marooned, cut off by the tide of post-war disillusion from the shore which he so confidently left, and gazing with a puzzled and aggrieved expression at the unfamiliar and defeatist sea."

This is a true picture of what all too many settlers feel, not in Kenya only. But, while it is true that for economic and political, and even deeper reasons, there has been a great and subtle change in English views on racial questions, it is wrong to describe this new attitude as one of 'defeatism'. It is by no means certain whether it is not the 'die-hard' who is the more guilty of defeatism, than the man who adjusts his point of view and his methods to an ever-changing world, and retains his faith in the ideals of British freedom, initiative and adaptability, finding new methods—often merely new forms and phrases—to continue that leadership and influence which will carry us even further to success as the people who have shown the greatest genius for colonisation in human history. The die-hard is the defeatist because he thinks we can only succeed on the basis of the old pre-War conditions, and in the pre-War environment. Nobody so young and so intelligent as Mrs. Huxley need really despair of our Imperial future.

W. ORMSBY-GORE.

Atmospheric Physics

Vorlesungen über Physik der Atmosphäre
Von Prof. Alfred Wegener und Prof. Kurt Wegener. Pp. xii+482. (Leipzig: Johann Ambrosius Barth, 1935.) 36 gold marks.

IN 1911 there appeared an attractive and highly individual book by Alfred Wegener, entitled "Thermodynamik der Atmosphäre". Under this somewhat forbidding title a wide range of atmospheric topics was discussed, with originality and insight if not always with adequate critical judgment. The book met with a favourable response, and was reprinted without alteration in 1924 and 1928, circumstances preventing the author from making the changes and extensions called for by the advance of knowledge. Meanwhile Wegener achieved world-wide fame as the author of the hypothesis of continental drift, which he expounded in a well-known and much discussed book; he also led a number of scientific expeditions, and unfortunately, in the last of these, to Greenland, he met his death.

Wegener had planned to expand his "Thermodynamik der Atmosphäre" into a more comprehensive book on the physics of the atmosphere, and among his papers the preface to this proposed work was found, of date 1928–29; it is a modest statement of his aim to produce not a detailed treatise but an introduction to the subject, individual in outlook. His brother, Kurt Wegener, who took up the leadership of the ill-fated Greenland expedition and published its results, undertook also, as a pious obligation to his brother's memory, to execute the transformation of the "Thermodynamik" into a "Physik der Atmosphäre".

This book is now issued, under the joint names of the two brothers. The author has evidently found the writing of the book a long and arduous task, as is really inevitable from its wide scope. Much of the original work is retained, including about half of the 143 illustrations in the original, supplemented with others to a total of 192 in the new book; the old illustrations, many of them very attractive pictures of clouds, waterspouts and other such phenomena, are indeed better reproduced now than before. The old material has, however, been much rearranged, and the original book is increased in size by about fifty per cent (from 331 to 481 pages) by the addition of new matter.

The new material includes a lengthy account—of about 35 pages—of the Milankovitch theory of solar radiation in the earth's atmosphere, and extended treatment of friction (eddy viscosity) atmospheric optics, atmospheric electricity and other topics. The author in his preface expresses his dissatisfaction with the chapters on radiation and on friction: the inclusion of the theory of Milankovitch in the former chapter certainly seems out of line with the general plan of the book, which is elsewhere substantially non-mathematical.

The task which the author has attempted is one of considerable difficulty, and perhaps one not intrinsically congenial, being undertaken mainly out of respect and affection for the memory of a brother. It is therefore with both sympathy and regret that the reviewer feels constrained to express an adverse opinion on the execution of the task; the more so since the book shows a commendable lack of national bias in its choice of matter and of references to authors. The inadequacy of the book in its new form lies in its undue retention of old points of view, and the lack of mention of very much new work done since 1911. It is true that there are a few references of very recent date, including the 1934 paper of Götz, Meetham and Dobson on the mean height of the ozone layer; but the author does not seem really familiar with several of the advances made in atmospheric physics during the last quarter century. A few illustrations of these statements may be cited.

One of the individual peculiarities of Alfred Wegener's "Thermodynamik" was his postulation of a hypothetical element, geocoronium, as constituting, with hydrogen, the upper layers of the atmosphere, from about 100 km. upwards; an atomic weight of 0·4 was suggested for this element—a value which the subsequent progress of physics has wholly ruled out. It is astonishing to find A. Wegener's original height-composition diagram, including this element, reproduced in 1935, even though the anachronism is mitigated by the (inadmissible) suggestion that geocoronium may now be identifiable as electron gas, or may not exist at all. The few pages of discussion of the composition, pressure and temperature of the atmosphere at great heights are in part incorrect, and generally inadequate. The works of Jeans, Milne and Lennard-Jones on the escape of atmospheres, and those of Lindemann and Dobson on the temperature as indicated by meteor observations, are not mentioned; nor is the possibility, now widely favoured, that mixing keeps the composition uniform up to about 100 km. (except as

egards water and ozone). The few pages devoted o planetary atmospheres are also rendered out of date by later work of Slipher, Russell, and of he Mount Wilson Observatory.

Similar criticisms may be made of the treatment of the auroræ and of iridescent and of luminous night clouds. Størmer's recent important work on these two types of high cloud, in which he has measured their height and motion by the methods long successfully applied to the aurora, is not cited: nor is his important discovery that very high auroræ lie in the high sunlit region of the atmosphere. The account of the present state of knowledge as regards the auroral spectrum is likewise unsatisfactory.

Turning to the more generally studied fields of meteorology, examination of the chapters on the mechanics of the atmosphere, in which air waves and clouds of wave-like form are discussed, shows that the Helmholtz theory of these clouds is described, without reference to the work of Rayleigh, Bénard, Idrac and G. T. Walker and his school, on vortical and shear motion in unstable layers of fluid; yet this work seems to offer a more satisfying explanation of a wide variety of cloud forms.

The chapter on radiation, which contains a long account of the theory of Milankovitch, makes no reference to the important work of Simpson, based on Hettner's study of the spectrum of water vapour; likewise the work on lightning, due to Simpson, C. T. R. Wilson and, in Africa, by Schonland, is not cited in the chapters on atmospheric electricity. It is, of course, impossible to deal in detail with a wide variety of topics in a book of this size, but to the reviewer it seems that some brief account of such recent advances should have taken the place of out-of-date or less important matter that is included.

This general criticism can be illustrated also by the results of an examination of the author's index. The name of Fabry, for example, is naturally looked for, not least on account of his very important work on atmospheric ozone: the one reference to his name is found, however, to be to a determination by Fabry and Perot of the viscosity of air—for which, surely, the most recent value, taken from one or other of the most modern tables of physical constants, should have been cited. Perhaps the strangest feature of the name index, however, is that Isaac Newton is quoted only as the author of the notation $\dot{x}$ for Leibniz's dx/dt, while his formula for the velocity of sound, and his law of friction, are attributed to H. A. Newton, a writer on meteors! The date of the latest reference to meteors seems, by the way, to be 1893.

These illustrations of points of criticism necessarily refer only to a fraction of the book; but they seem to the reviewer to be too typical of the whole. The high purchase price might certainly be laid out to better advantage by seekers after knowledge of atmospheric physics.

S. CHAPMAN.

Through Einstein's Eyes

The World as I see It
By Albert Einstein. Translated by Alan Harris. Pp. x+214. (London: John Lane, The Bodley Head, Ltd., 1935.) 8*s*. 6*d*. net.

THIS book ought to be entitled 'The World as I feel It', so suffused is it with a deep sincerity and a passion for justice. To Einstein the world is a painful place, not merely because of the suffering that abounds but also because of the latent possibilities for good that man creates and ignores. Jews are persecuted, driven and hunted from the lands of their adoption to which they have contributed so generously in art, in science and in literature. Einstein sees the dignity of civilised human beings humiliated, and their bodies physically maltreated for their political views or racial descent, and as a sensitive human being he suffers with them in shame. Art slips into decadence, science is circumscribed, political leaders lose their independence of spirit and the ordinary citizen his sense of justice. Masses, worked into fury by unscrupulous newspapers, don uniforms to kill or be killed for worthless aims, and nations arm for war on a colossal scale, while their leaders chatter of peace. All this Einstein sees and it tortures him.

Whatever coherence this book possesses is of an emotional or an aesthetic nature; no attempt is made by the distinguished author to construct a consistent sociological background against which to view the multitude of problems that arise on every page. He stresses the contradiction in social organisation, that machinery should intensify rather than moderate the struggle for existence, that science should be used for war and destruction, and he pleads for a planned subdivision of labour as the solution. Coupled with this he would make a call to the economically stronger members of

the community to arrest the threatening decay of scientific life; but there is no discussion of the obstacles in the way of such a simple solution. It is an emotional rather than an intellectual analysis. Such questions occupy four of the five parts into which the book is divided.

It is in the last part that Einstein turns to matters more specifically scientific. Here he discourses very briefly on a variety of methodological and philosophical topics: scientific truth, methods of theoretical physics, various aspects of relativity; Kepler, Newton, Clerk Maxwell, Bohr, Planck, and many others. Many parts of it were delivered as lectures to various bodies. Here again the transparent sincerity of the man shines through everything he writes.

Experience, according to Einstein, is the alpha and omega of all our *knowledge* of existence, but the reasoning mind makes its specific contribution in the logic of science, and that contribution lies in the basic concepts of mechanics. Every attempt at a logical deduction of these basic concepts from elementary experience, he argues, must be doomed to failure; they are creations of the imagination, not given realities. Pure thought nevertheless can grasp reality, but in the last resort experience must always remain the sole criterion of the utility of any such mathematical construction. The mind grasps this reality that exists outside it, and creates in addition basic concept by means of which it organises and understands that experience. The mind is thus a creative force in Nature, but there must exist an external reality upon which it must operate.

The treatment at this level would have been complete, in broad outline at any rate, had Einstein recognised the significance of the question suggested by the evolutionary outlook, namely, how far the mind of man is itself restricted and conditioned historically by the objective world, and thus how far the validity of the logic of science is affected by the fact that the reasoning capacities of man, although presumably ever-sharpening are nevertheless never perfect. In this way would the problem have been raised whether these basic mechanical concepts that serve in science to unify experience are indeed 'free' creations of the imagination.

H. L.

Ideal and Real Crystals

Ideal- und Realkristall

(Sonderheft der Zeitschrift für Kristallographie, Band 89, Heft 3–4.) Pp. 193–416. (Leipzig: Akademische Verlagsgesellschaft m.b.H., 1934.) 17.60 gold marks.

WHEN one of the editors of the *Zeitschrift für Kristallographie* received almost simultaneously two papers on the above subject, it occurred to him that a valuable opportunity had arisen of securing an adequate review and discussion of this important topic by devoting to it a separate issue of the *Zeitschrift*. As a sequel to this happy inspiration, a double-number has now appeared, which contains an introduction by Prof. Niggli himself, followed by thirteen papers and one shorter note on the same subject. The papers are all printed in the language in which they were written, with the result that half of them are in English and half in German.

The series of papers opens with an important contribution by Prof. Buerger, from the Massachusetts Institute of Technology, on "The Lineage Structure of Crystals", in which he demonstrates the widespread occurrence of a phenomenon analogous to dendritic or arboraceous growth, giving rise in massive crystals to a structure which appears as a 'mosaic' when viewed only in two dimensions, but is often a complex three-dimensional structure of nearly parallel branches springing from a single stock or nucleus. The impression thus created, that crystal structures are predominantly tangled, is happily corrected by a final brief note by Dr. Buckley, from Prof. W. L. Bragg's laboratory in Manchester, in which he shows that crystals of potassium sulphate, grown in a thermostat in presence of a dye-stuff, and allowed to dry without the assistance of filter or blotting paper, can be obtained in a state of such perfection that magnificent interference patterns between parallel faces can be observed with monochromatic light. Many other examples of a similar character are cited, and it is clear that the imperfections, which formed the original subject of discussion, are far from being universal, and that real crystals can in fact approach very nearly to the ideal.

Limitations of space forbid any reference to the other papers of the series, but it is to be hoped that the unfavourable rate of exchange, which increases the price to English readers to about thirty shillings, will not prevent them from being widely read and studied in Great Britain.

T. M. L.

aläogeographie: mit besonderer Rücksicht auf die ehlerquellen

'on Dr. Fritz Kerner-Marilaun. Pp. viii+410. Berlin: Gebrüder Borntraeger, 1934.) 30 gold marks.

ıs palæogeography is a composite science which erves to co-ordinate stratigraphy, palæontology and ectonic geology, the palæogeographer must be con-ersant, not only with the aims and methods of these ›ranches of geology but also with the possible ›ources of error which may arise. We already possess ›everal excellent standard treatises on palæogeo-graphy, such as the classical works of Arldt and Dacque, which follow more or less conventional lines. The author of the present book, however, approaches his subject from an entirely different point of view by discussing the problems with special reference to the possible sources of error.

The book is divided into four parts. Part 1 deals with the sedimentary rocks and the criteria to be applied in determining the conditions under which they were formed. It provides an up-to-date discussion of the problems of sedimentation, and a most instructive section is that dealing with the many errors possible in the recognition of desert deposits. Part 2 is devoted to correlation and the use of fossils both in the correlation of beds and in the determination of sedimentary environment. Part 3 is a modern presentation of the various theories of mountain building, including a discussion of Wegener's theory of continental drift.

Part 4 includes about one third of the entire book and is devoted to palæocartography. The author here stresses the importance of distinguishing clearly between palæogeographic investigations in unmoved areas in which the palæogeographic lines can be projected, without error, on to the present maps, and investigations in areas which have suffered lateral translation by folding or thrusting. In the first case the sedimentary rocks occur in the areas in which they were originally deposited but, in the second case, their original regions of deposition lie at a greater or lesser distance from their present position. This movement factor is one which often escapes recognition, and the author has performed a great service in directing attention to it.

Altogether the book should prove of great use and value to geologists working in many different fields, but it is of an advanced nature more suited to the needs of the research worker than those of the student.

The Handbook of Palestine and Trans-Jordan

Edited by Sir Harry Luke and Edward Keith-Roach. Third edition. Pp. xvi+549+1 map. (London: Macmillan and Co., Ltd., 1934.) 16*s*. net.

Conditions change with such rapidity in modern Palestine that it is not surprising that very considerable revision has been necessary in the preparation of the new edition of "The Handbook of Palestine and Trans-Jordan". Information and statistics have been brought up to date, and, to quote Sir Arthur Wauchope's introduction, it now "gives a full account not only of the country's past, but of the achievements and changes of the last four years".

In view of the interest of Palestine's prehistory, it is a pity that the section dealing with this subject has not been more adequately revised. Miss Garrod's more recent discoveries are not completely covered, though, presumably, the final revision of the text had not been made before some, at least, were available for inclusion, while Sir Flinders Petrie's work in the neighbourhood of Gaza is barely mentioned. The important results obtained at Tell Duweir do not appear at all. Hence the largest Tell of archæological importance in Palestine does not appear on the map, while its identification with Lachish, now certain, entails correction of both map and text.

These, however, are perhaps minor blemishes, where so much ground is more than satisfactorily covered. The handbook continues to be a never-failing source of information on the geography, history and social and economic conditions of the country.

Hutchinson's Technical and Scientific Encyclopædia: Terms, Processes, Data, in Pure and Applied Science, Construction and Engineering, the Principal Manufacturing Industries, the Skilled Trades; with a Working Bibliography, naming Three Thousand Books and other Sources of Information, under Subjects. Edited by C. F. Tweney and I. P. Shirshov. In 3 vols. Vol. 2: Direction of Rotation to Hydrogen-Ion Concentration. Pp. ii+673–1344. (London: Hutchinson and Co. (Publishers), Ltd., 1935.) 28*s*.

Much credit is due to the editors of this "Encyclopædia" for the design and execution of their work. So many subjects may be regarded as "technical and scientific" that to endeavour to afford appropriate information upon all matters pertaining to them, not only for scientific workers and technologists, but also for intelligent inquirers among the general public, would seem almost an impossible task. So far, however, as is practicable within the limits of three volumes, and judging by the contents of the two volumes already published, the editors will achieve their purpose. In the present volume, for example, sixty-seven pages are devoted to electrical subjects from "Electric Cables" to "Electrostatic Units". Glass and glass manufacture occupy twenty pages; dyes, eight pages; hormones, four pages (we note, by the way, that the word endocrine is not indexed); glucosides, eight pages; furnaces, nine pages; gem-stones, six pages; and geophysics, four pages. We have tested the volume for many words and terms used in various branches of science and technology, and have rarely been disappointed. Many biological terms are included but no attempt is made to cover this whole field, though "commodities of botanical and zoological origin are named and described". This accounts, perhaps, for the omission of 'gene' and 'genetics'.

No work of the same scope and standard has been issued in England for many years; and we congratulate the editors and publishers upon their production, which should find a place in every reference library.

Continuity of the Solid and the Liquid States

By Prof. J. Frenkel, Physico-Technical Institute, Leningrad

IT was believed until quite recently that liquids were in all respects—save their density—more similar to gases than to solid bodies. This belief was strengthened by the van der Waals' theory of the continuity between the liquid and the gaseous states, the sharp transition between them (corresponding to the boiling or condensation point) being replaced by the hook-like portion of the $(p–v)$ curve, representing unstable intermediary states.

Recently, a number of new facts have corroborated the view that liquids—at least in the vicinity of the melting point—are much more similar to solids than to gases, not only with regard to density, but also with respect to the character of the *heat motion* and *structure*. As I pointed out ten years ago[1], the heat motion in simple liquids consists of vibrations about an equilibrium position which after an average time $\tau=\tau_0 e^{U/kT}$ (τ_0 is vibration period, T is temperature, U is activation energy) is shifted through a distance δ comparable with the interatomic distances. Under the influence of alternating forces with a period τ' much larger than τ, the liquid behaves in the ordinary way, displaying a viscosity coefficient $\eta=N\tau$, where N is a constant which can be defined as the rigidity modulus displayed by the same 'liquid' when subject to alternating forces with a period τ' much smaller than τ (amorphous solids are rightly denoted as supercooled liquids with a very large 'relaxation time' τ).

Still more recently, it has been pointed out (for the first time by Pauling) that the molecules in a crystalline solid can rotate more or less freely—just as has been assumed for liquids and gases; while Debye has shown[2] that both in liquids and solids there is actually no *free* rotation, but a sequence of rotational oscillations about an equilibrium orientation which is changed abruptly from time to time[3].

Finally, it has been shown—for the first time by Stewart—that the X-ray diagrams of liquids, especially in the vicinity of the melting point, are very similar to those of a microcrystalline solid. The process of melting, therefore, cannot be conceived as a sharp transition from the crystalline to the amorphous state: the liquid near the melting point is still to a great extent crystalline and becomes gradually more and more amorphous as the temperature is raised. On the other hand, a solid crystalline body, especially in the vicinity of the melting point, is no longer exactly crystalline, but contains a number of 'dissociated' atoms or ions which are irregularly distributed in the 'interstices' of the crystal lattice, and form the beginning, as it were, of the amorphous phase within the crystal. This 'dissociation' process explains diffusion in solids and the electrical conductivity of ionic crystals[4].

Thus we see that the usual conception of the existence of a fundamental difference between the solid and the liquid states is incorrect. I wish to put forward the contrary view, namely, that *the solid and liquid states are connected with each other in a continuous way, just as are the liquid and the gaseous states.* The fact of the existence of a sharp transition point between the solid and the liquid states does not in the least contradict this conception—just as the existence of a sharp boiling (or condensation) point does not contradict the continuity between the liquid and the gaseous states. It simply indicates that, just as in the latter case, a continuous transition from solid to liquid, corresponding to a gradual increase of volume and of the degree of amorphism, must go through a sequence of unstable states, characterised by the same hook-like shape of the pressure (p)–volume (v) curve, as that occurring in van der Waals' isotherms below the critical temperature. Hertzfeld and M. Göppert-Mayer[5] have indeed shown that the $p–v$ curve for a number of crystals displays a minimum of pressure, which they interpreted as corresponding to the melting point. They were led to this interpretation—or rather misinterpretation—by the fact that solids cannot be superheated, in contradistinction from liquids. This law of analogy between the melting and the boiling process can, however, be very naturally explained by the fact that small liquid drops formed inside the solid cannot rise to the surface, as do the gas bubbles formed in a boiling liquid. Melting can therefore begin effectively at the surface only.

A more exact theory of the $p–v$ isotherm for a crystal shows that the minimum of p discovered by Hertzfeld and Göppert-Mayer is followed by a *maximum*, so that we actually find a condition quite similar to that which is described by van der Waals' theory of the amorphous state. In order to build up an exact theory of fusion, it is necessary not only to consider the dependence of the vibration

quency of the atoms (or molecules) on their an distance apart more exactly than this has n done by the above authors, but also to take o account the *gradual amorphisation* of the ly, which begins long before the melting point reached. This 'amorphisation' can be regarded the result of a large number of *local and tem-rary ruptures of the body*, due to the increase of interatomic distances. To make this point ar, let us imagine that three atoms are put in ine and the distance apart between the two end oms is gradually increased. Then the middle om, which in a state of lowest energy should at e beginning lie just midway its neighbours, will ually move towards one of them, since the iddle position, which initially corresponded to a inimum of the potential energy, will finally rrespond to its maximum. The same result as at due to external forces, pulling the end atoms opposite directions, must be produced by heat otion. To compare the two effects, however, we ust consider not the *average* distances between ie atoms as determined by the thermal expansion, ut the maximum distances connected with iermal oscillations. It can thus easily be shown iat a one-dimensional crystal with increase of emperature will not 'melt' but will break up ito a number of small pieces (single atoms and oublets). In a two- or three-dimensional solid, a ocal 'rupture', however, will not lead to a breaking p of the whole body, thanks to the existence of ateral bonds between the atoms.

Although such local and temporary ruptures nust take place also in a solid body, their number nd importance greatly increase on melting, vhich accounts for the very much larger degree of amorphisation' which is found in the liquid state. This explains also the fact, first noticed by Rashevksy[6], that the latent heat of fusion is of the same order of magnitude as the elastic energy of the corresponding body strained to its theoretical breaking point at the zero point of temperature.

We thus see that the three states of aggregation of matter—the solid, liquid and gaseous—must be regarded as forming *one continuous sequence*, the sharp transition points—melting or boiling—being simply substitutes for continuous transitions through unstable intermediate states, corresponding to the hook-like parts of the p–v curve. At ordinary temperatures there are two such hook-like portions, the first one (for smaller v's) corresponding to the melting, and the second to the boiling point. Above a certain temperature T_1—the ordinary critical temperature of the substance—the second hook disappears, whereas the first one remains, since, as has been shown by Bridgman, and especially by Simon, it is possible to obtain under sufficiently high pressure a substance in the solid state above its critical temperature. A critical temperature $T_2 > T_1$ for which the first hook should also disappear does not exist (according to Bridgman the melting temperature displays a monotonic rise with increasing pressure). It is, however, very probable that there exists a critical temperature $T_0 \leqslant T_1$ (connected with a strongly *negative* value of the pressure) at and *below* which the first hook should disappear—corresponding to the fusion of the solid and liquid states into a single 'condensed' state.

A detailed mathematical treatment of the above questions will appear shortly elsewhere (in the *Jour. Phys.*, or the *Acta Phisicochimica USSR*).

Human Origin and Christian Doctrine

By Dr. W. D. Lang, F.R.S.

THE late Bishop Gore remarks, in his "Belief in God", that it is not so much about the existence of God that men dispute, as the nature of the God in whom they can believe. Sir Ambrose Fleming, in the second published edition of his presidential address to the Victoria Institute, on "Modern Anthropology *versus* Biblical Statements on Human Origin", takes a less tolerant view. In his belief, as he states it, that "adherence to the doctrine of [organic] evolution is entirely inconsistent with belief in the fundamental doctrines of Christianity . . .", he appears rather to embrace in one atheistical category all who do not subscribe to this belief; such, at least, is the irresistible impression one receives on reading his address. This premise, which at best can have but an individual, and not a general, application, will be further considered: but first, all who admit the transmutation of species—and they are a heterogeneous assemblage, and must include, besides

modernist churchmen, churchmen as orthodox as Bishop Gore, educated laymen, Christian and non-Christian, agnostics, atheists, and even early churchmen like St. Augustine—must settle down together and consider the rest of Sir Ambrose's discourse.

Two main themes, like the narratives in the early chapters of *Genesis*, run through the thesis, namely, the inadequacy of palæontology in general, and of anthropological palæontology in particular, to prove the transmutation of species; and the inadequacy of natural selection as a means of transmuting species. It is clear that, if the first point is admitted and the transmutation of species is thereby considered as disproved, it is meaningless to labour the second; yet both points are laboured, though somewhat intermingled, in a series of arguments, from which, perhaps, one on each point stands out more emphatically than the rest. If, says Sir Ambrose, in effect, transmutation of species has taken place, transitional forms would be commoner than they are; and he points especially to the few known remains of supposed man more primitive than *Homo sapiens*. It is probable that those who have had most experience of fossils, both in the field and in the study, would say that, considering the long succession of fauna after world-wide fauna presented to palæontologists, considering the comparatively few accessible exposures of rocks of any one age in the world, considering the small chances of any organism of any given age being preserved as a fossil, and, comparatively speaking, the very small amount of intensive and extensive collecting that has been done, it is wonderful how notably fossil species *are* found to intergrade; and they would probably agree that all the evidence points to there having been a transmutation of species. The chances against any organism, and especially a bony organism, being preserved as a fossil, also tells against Sir Ambrose's contention that the associated remains of *Pithecanthropus* and *Eoanthropus* do not belong, respectively, to one individual.

Again, Sir Ambrose argues that the apparent rate of increase in the population of the world is a datum for estimating the age of the human species; and he holds that thus it can be proved that the inconceivably long periods demanded by the Darwinians for the evolution of man are impossible. He does not accept the contention of Malthus and Darwin that populations are equilibrated by their environment, and that once the bands of a controlling environment are loosed, even the slowest-breeding species will increase by leaps and bounds—a supposition which is corroborated by observing the sudden and immense fluctuations in some recent animal populations, human races included, the causes of which, if not understood, are almost certainly environmental in the widest sense of that term. Were this not so, the whole world must have been filled with human inhabitants again and again, even in the comparatively short time allowed by Sir Ambrose Fleming since man's creation.

This ground has, however, been gone over many times; nor does it go to the root of Sir Ambrose Fleming's difficulties, as is clear from the following passage:

> "In rejecting the idea of Creation by Divine Will and Power, the evolutionist then claims that the only kind of beginning which can be accepted as true is one which appeals to his own finite intelligence. He is prepared to accept the Darwinian hypothesis because it is intelligible to him. . . . He rejects as untrue any statements about Nature which lie outside the limits of present human understanding and experience. . . . Thus, said an eminent naturalist, . . . 'the theory of evolution was a theory universally accepted, not because it could be proved to be true but because the only alternative, special creation, was clearly incredible' ".

Surely this passage goes to the heart of the matter, and reveals a misappreciation both on the part of Sir Ambrose and of his supposed opponents of the self-limitation of science. If it is true to say that a science is a marshalling of observed facts (a natural science, of observed physical facts) with the view of drawing logical inductions from them, it is clear that a natural science is self-limited, in its material (observed facts), in its method (logic), and in its standards (physical values). It must proceed from immediate effects to proximate causes, and so feels its way back to origins. It 'explains' the end by the beginning. It is otherwise with philosophy, which has its scientific aspect, and in this light might be called the science of significancies; but its material is all experience, and its standards are metaphysical values. It does not 'explain' the end by seeking its origin, but believes that the end 'explains' the beginning.

It is clear that, in the passage quoted above, Sir Ambrose Fleming is standing on metaphysical ground, and when he complains that his opponents reject "any statements about Nature which lie outside the limits of present human understanding . . ." he is really expecting them, as natural scientists, to go beyond the limits imposed by their system. They should answer that they must play the game, and seek proximate causes before they can feel back to ulterior causes, least of all adduce an ultimate cause. When, moreover, he points out that their arguments do not prove an anthropoid origin for man, they would answer

t such a biological theory, by its very nature, incapable of mathematical proof, but must end, like most such questions, on a balance probabilities; and that is what Prof. Watson ant, in the passage quoted by Sir Ambrose, in ring that special creation was incredible. On other hand, Sir Ambrose would be right in iming that, as natural scientists, they are in-mpetent, through the very limitations of their thod, to disprove the existence of God. In ner words, Sir Ambrose and his opponents speak ferent languages, and on terms on which agree-ent is impossible.

We are thus brought back to Sir Ambrose's emise, that the acceptance of the doctrine of ganic evolution is entirely inconsistent with the ndamental doctrines of Christianity. But, in mplete sympathy with his ultimate conclusions, ith genuine respect for his courage in upholding em, and in no self-complacent or dogmatic pirit, a Christian may yet ask what clause in the hristian creeds forbids him to be an evolutionist? Why may not a Christian believe, with the early hurch, that the story in *Genesis* of man's creation focused upon the spiritual truth that God reated man, and is not to be regarded as a scientific ccount of the process? Why, if he honestly follows intellectual truth, may he not trust God not to lead him to intellectual confusion; and, although he cannot expect to solve all his intellectual difficulties, just because, as Sir Ambrose insists, his mind *is* finite, why may he not hope, like Job in similar circumstances, ultimately to gain a vision of God?

After all, what differentiates a Christian is what he thinks of the person of Christ, and this seems to bear but remotely upon the physical processes of creation. On this criterion, it must be admitted that the greatest evolutionist cannot be claimed as a Christian—"I gradually came," Darwin said, "to disbelieve in Christianity as a divine revelation"; on the other hand, he repudiated atheism. His life, however, largely belied the statement just quoted. For the Christian's God is also eminently expressed in all that is beautiful, good and true. Now, on his own showing, Darwin gradually lost his æsthetic faculty, as he gradually lost his Christian faith; but every page of his writings expresses that wide charity which is the hall-mark of goodness; while his life was a single-minded pursuit of truth. Surely, Sir Ambrose will allow that such a man, although an evolutionist and in spite of his disavowing Christianity, is yet not far from the Kingdom of God.

Poison Gas

THE menace to civilisation of attacks on cities from the air is naturally perturbing all the peoples of Europe, for it is generally agreed by those best able to judge that there is no effective means of defence, so that the attacked country would be obliged to retaliate on the cities of the aggressor. It is true that the use of gas in war was prohibited by the Geneva Gas Protocol of 1925, to which most of the principal powers of the world subscribed; but in view of the failure to effect general disarmament there is even less confidence in the protocol now than there was in 1925. The attack might be made by dropping bombs filled with high explosive, or incendiary composition or with gas, or gas might be sprayed. In the Great War gas was not used in this way, and consequently it is not possible to say from actual experience whether it would be more effective than high explosive.

Against troops who had been trained in the use of gas masks and other protective measures the statistics, so far as they go, indicate that gas shells cause about as many casualties as the same number of H.E. shells, but that they kill far fewer. The civilian population of a city could not be trained in protective measures to the same extent, and a large proportion would not have gas masks; but, on the other hand, they can take refuge in the houses, and so it should be possible to restrict the casualties. So far as can be judged in the absence of actual experience, these should be considerably less than those which would be caused by an equal weight of H.E. bombs. Probably the greatest damage, both physical and moral, would be done by squadrons of low-flying planes spraying gas followed immediately by others dropping H.E. bombs. If such an attack were delivered on a day when there were low clouds above which the approach could be made, and into which the attackers could dash again after the assault, it would not be possible for the defending fighting planes and anti-aircraft guns to accomplish much against them. If air raids should be made again in the future, they would, of course, be on a vastly greater scale than in the War. Consequently, it would be more possible to produce a lethal concentration of gas over such a large area as is needed for a decided military effect.

Hence the importance of educating the public in measures which would reduce the casualties to a fraction of the figure they might otherwise assume.

At the annual meeting of the British Science Guild held on June 12, a lecture[1] on gas defence was given by Mr. Davidson Pratt, general manager of the Association of British Chemical Manufacturers, and formerly an official in the Chemical Defence Research Department. Mr. Pratt dealt at fair length with the question of gas-protected rooms, of which he considers there should be one in every house or building, preferably situated on an upper floor. The preparations advocated would be decidedly troublesome and expensive, as they would involve not only closing all cracks and chinks with putty or mud, but also boarding up the windows outside and covering them inside with stout material such as wetted blankets or linoleum; also laying in a store of provisions, water and other necessities. It is evident that it would be difficult to do all this even in the houses of the well-to-do, and would be practically impossible in those of the poor. We should like to know whether these recommendations are based on actual experiments, and whether it would not be possible to make a room reasonably safe without rendering it useless for any other purpose than a refuge in emergency. If such experiments have not been carried out they should be put in hand, and the results published.

As regards gas masks, Mr. Pratt recommends that a type should be developed less expensive than the service one but sufficiently efficient for the needs of the general population. It is unsatisfactory that so little appears to have been done yet in this direction. The problem of clothing that will protect against mustard gas and lewisite is more difficult. Other subjects dealt with briefly in the lecture were the detection and diagnosis of gas and decontamination; but apparently, from what Mr. Pratt said, the methods and organisation required have not yet been worked out.

An anonymous pamphlet on this subject has also been issued by the Union of Democratic Control[2]. Considerable industry has been shown in collecting statements, but the comments of the writer are mostly misleading, so obviously misleading that they tend to produce in the reader a prejudice against pacifists rather than a hatred of war, which is the natural attitude of most Britons.

The chapter dealing with Mr. Davidson Pratt's lecture is headed "The Great Defence Hoax", and the general thesis is indicated by the statement on p. 60: "The authorities hope to succeed in rousing enough fear amongst people to persuade them to acquiesce in an armaments race, to make the danger of air attacks seem real and to encourage them to believe that the precautions against them will be effective". More agreement will be felt with the following sentence, which occurs almost at the end of the pamphlet: "The plain fact is that the only defence against air attack is the absolute prevention of war". Similarly the only real defence against burglary is the absolute abolition of burglars, but pending that our front doors are provided with latches.

Obituary

Prof. J. B. Cohen, F.R.S.

IN the old organic chemistry laboratory at the University of Leeds there was a life-size bust of Liebig. It was perched high up on the top of some reagent shelves and it seemed as if the great 'master' of organic chemistry looked down and said, "All is well here". In many ways that bust was symbolic of the sway exercised in the laboratory by J. B. Cohen. He would have wished no better thing to be said of him than that he had tried to carry on the traditions made by Liebig for organic chemistry in the eighteen-fifties. Nicknames are often given to professors by their students as a sign of affection, but Cohen never received one from his. He was a little too austere for that. Instead he was usually called "Julius"—his first name. In a sense this was a greater sign of affection. It struck a deeper note of regard.

Cohen was born in Manchester in 1859 and lived almost the whole of his life in the north of England. Except for a couple of years in Munich in Baeyer's laboratory, he spent all his active scientific life in the Owens College and the Yorkshire College (later the University of Leeds). He went to Leeds in 1890. Previously, he was a demonstrator of chemistry at Owens College. His title at Leeds was lecturer in organic chemistry, and in 1904 he was appointed to a chair. Twenty years later he retired, having reached the age limit. He was made a fellow of the Royal Society in 1911. But when he retired he did not give up active work. During the next eight years he occupied a small suite of laboratories in the Leeds Medical School, and carried out a most laborious investigation on the antiseptic and trypanocidal activity of a large series of synthetic compounds, many of which he prepared himself. This was done

er the auspices of the Medical Research Council. n the last-named body decided to discontinue line of work, Cohen really did retire, and he and wife left Leeds and went to live at their country age near Coniston Lake. It was there amidst the itiful surroundings which he loved that he passed y on June 14, after a few weeks' illness. He was seventy-six years of age.

ohen taught by example rather than precept. research students will always retain ineffaceably heir minds a picture of his amazing industry, his technical standards, his almost woman-like tleness in dealing with their early errors, his cent smile at anything which amused him and his orrence of anything which savoured of showman- or attaining ends by any but transparently est means. Those who came less closely into ch with him will remember his clarity as a urer, his great interest in the welfare of students especially foreign students of the University, Working Men's Club which he founded and per- ally conducted in one of the least attractive parts Leeds, and not least his attempts by direct investi- ion to show the great evils wrought by the smoke- en atmosphere of our industrial towns.

Cohen was an artist to his finger tips. A lover of sic, he was no mean performer on the violin. He his wife often gave delightful musical evenings their friends both in the University and outside it. painted well in water-colour and got great enjoy- nt in trying to put on paper in this medium his pressions of many parts of his beloved Lake strict. With such a temperament his likes and likes were often very clear cut. They were some- nes an enigma to those who did not know him, but ver to his friends. Few men are so honest and live eir lives with such simplicity and dutiful routine Julius Cohen did, and none can have tried more thfully or wholeheartedly than he to serve his low men.

As a chemist Cohen did a considerable amount of luable and fundamental work, but he did not ake the kind of outstanding discoveries that open new fields of activity. He was, however, very rsatile, and from the titles of his published papers may be seen that he covered a wide field. He was ne of the old school of organic chemists who were ainly interested in the structure of carbon com- unds and its influence on their properties and actions—what may be called molecular architecture d its significance. The principal province of his ork was that of aromatic substitution, especially benzene compounds, and the laws which govern it. It he was also intensely interested in the problems optical activity, and almost the last paper he ever ote was on "Asymmetry and Life".

It was this mystery of the optical activity of turally-occurring organic compounds, together th his great appreciation of the work of Pasteur, at probably directed Cohen's attention to the wide pe for chemical investigation provided by the tivities of living organisms. This led him to advise ny of his research students—the first being H. D. kin—to take up the study of what was then called physiological chemistry and is now named bio-chemistry. None who were so advised can have regretted their choice, and the enormous development of biochemistry during this present century proves how right Cohen was in his appreciation of the contributions that the chemist could make in the biological field.

Organic chemists owe a great debt to Cohen because of his books. The smallest of these was probably the most important—his little "Practical Organic Chemistry". There was no book anything like as satisfactory when it was first published, and it has guided innumerable students in their first steps in the subject. Indeed it is still widely used. His greatest production was the three-volume "Advanced Organic Chemistry", and it is a tribute to his industry and wide reading that he could write such a book and yet carry out his normal day's work at his bench in the laboratory. Organic chemistry is now almost getting beyond the compass of a one-man book, but this "big Cohen" is still one of the books which are highly valued by advanced students in Great Britain. To many, Cohen's books will be his most lasting memorial, but those who had the privilege of his friendship will always in addition be grateful for the virtue they derived from the man himself.

H. S. R.

Prof. Max Cremer

ON May 22, a few weeks only after celebrating his seventieth birthday, Max Cremer, emeritus professor of physiology in the University of Berlin and formerly head of the Physiological Institute of the Veterinary College, Berlin, died in Munich. He was one of the last representatives of the classical German school of physiologists who mastered both biochemistry and biophysics.

Cremer started his scientific career as a pupil of Carl Voit and Soxhlet by investigating animal metabolism, particularly the formation and utilisation of carbohydrate in the body. He succeeded in proving that the organism is able to synthesise glucose and glycogen from certain breakdown products of organic matter, for example from glycerine. Although he maintained a fruitful interest in these problems, he soon turned his main activities to electrobiology, a field very congenial to his talents in mathematics and physics. In 1906, he discovered the existence of considerable potential differences between suitable watery electrolytes separated by a phase immiscible with water (glass, nitrobenzene). This fact formed the basis of the present view of electrical phenomena in living matter, and on the practical side, of the use of the glass electrode for hydrogen ion measurements.

Regarding the electric change in nerve as the essential factor concerned in the origin and propagation of the impulse, Cremer combined physico-chemical and physiological terms in an ingenious manner which culminated in a formula for the velocity of the impulse and in a mathematical expression for the processes preceding excitation. He also promoted the technique of recording the rapid

potential changes occurring in tissues (the invention of a string electrometer; the first physiological application of the cathode ray tube and the loop oscillograph in 1907 and 1912).

Although Cremer was extremely critical and even sarcastic in the scientific sphere, he was humorous and cheerful in ordinary life. This mixture in his imposing personality was very manifest in speech and discussion, and will not be forgotten by his pupils and friends. H. ROSENBERG.

WE regret to announce the following deaths:

Mr. C. T. Kingzett, one of the founders of the Institute of Chemistry, and author of the "Chemical Encyclopædia", and other books on chemistry, on July 29, aged eighty-two years.

Prof. W. R. Sorley, Knightsbridge professor of moral philosophy in the University of Cambridge, author of many well-known works on ethics, on July 28, aged seventy-nine years.

Mr. C. E. Stromeyer, chief engineer of the Manchester Steam Users' Association, president of the Manchester Literary and Philosophical Society in 1929–31, on July 23, aged seventy-nine years.

Prof. F. A. F. C. Went, For.Mem.R.S., extraordinary professor of botany in the University of Leyden, and emeritus professor of botany in the University of Utrecht, on July 24, aged seventy-one years.

News and Views

Dr. Griffith Evans

WE extend our congratulations to Dr. Griffith Evans, who will attain his hundredth birthday on August 7. Dr. Evans was a pioneer in the study of protozoology in connexion with infections, and the first man to associate trypanosomes with the production of disease. He was born at Tymawr, near Towyn, Merionethshire. After studying medicine for a short time with a medical practitioner at Towyn and Aberdovey, he entered the Royal Veterinary College, London, where he qualified as M.R.C.V.S. In 1877, he was sent to India in the Army Service Corps. It was there that his great work on blood parasites was carried out. On arrival in India, he was appointed to investigate an endemic disease which for many years had been fatal to cavalry and artillery horses; by microscopic examination of the blood, which revealed the specific bacillus in the blood of every patient, Evans at once proved the disease to be anthrax fever.

IN 1880, Dr. Griffith Evans's work on surra began; and upon studying the reports which had already been made upon the disease he at once reached the opinion that it was due to some parasite of the blood. His first act was to examine microscopically the blood of a surra patient: it was swarming with parasites. Though Koch had not yet made his classical postulates, and though Evans was ignorant of the nature of the microbes revealed to him, he immediately associated them with the production of the disease. They were the parasites which, at first called *Trichomonas evansi*, are now known as *Trypanosoma evansi*. Official opinion was strongly against him, but the Government printed his reports, and he had the gratification of knowing that his statements spurred on a number of younger men to continue investigations along lines which he had laid down. He returned to England in 1885, and after further work in Crookshank's laboratory, King's College, London, retired from the army in 1890. In 1917 he was awarded the Mary Kingsley Medal by the Liverpool School of Tropical Medicine, in recognition of his distinguished scientific work, and on that occasion he wrote a short autobiographical memoir, which was published in vol. 12 of the *Annals of Tropical Medicine and Parasitology*.

Alcohol and Road Accidents

EARLY this year, the Minister of Transport asked the British Medical Association whether it could usefully make any observations on the place of alcohol in the causes of road accidents, in the light of existing knowledge and experience. The Association thereupon appointed a special committee to consider the subject and the report of this committee has just been published (*Brit. Med. J.*, Suppl. July 27, 1935; p. 57). The committee confined itself to an examination of the scientific evidence on the effect of the consumption of alcohol on the functioning of the body, especially of amounts insufficient to produce the state commonly recognised as drunkenness. The Alcohol Committee of the Medical Research Council concluded that the direct effect of alcohol upon the nervous system is, in all stages and upon all parts of the system, to depress or suspend its functions; it is, in short, simply a narcotic drug. The earliest effects are an impairment of the faculties of judgment, concentration, self-criticism and the power of estimating risk, which are often accompanied by a sense of well-being and of self-satisfaction. At the same time, the power of making movements dependent on rapid and accurate co-ordination is adversely affected; the rapidity and accuracy of neuro-muscular co-ordination are diminished. The report reviews the experimental evidence on which the above statements are based, and points out that as little as three ounces of whisky produces these effects. The experiments were of course made in other connexions to determine the effects of alcohol upon the nervous and neuro-muscular systems; but

are applicable to motorists, whose movements are dependent on rapid and accurate co-ordination between the eyes, hands and feet. The committee also emphasises that the elimination of alcohol from the body is a slow process : 10–12 c.c., or the equivalent of one ounce of whisky, can be oxidised each hour, and the rate is not increased when the concentration in the blood is raised by drinking larger quantities. The committee concludes that the driving capacity of a driver, who has taken even small amounts of alcohol, must frequently be adversely affected, even when it has been consumed some hours before driving, and especially if taken in the absence of food.

Production of Oil in Great Britain

ONE of the most striking characteristics of the times is the tendency of man to make himself less dependent on the circumstances imposed by geographical conditions. Formerly it was necessary to settle, and for industries to develop, where sources of food and raw materials were readily accessible. Now the tendency is for these things to be done just where man chooses—but at a certain price. Modern civilisation demands oil and oil products, and our need is being in part met by the treatment of coal. In the House of Commons on July 24, the Secretary for Mines (Captain Crookshank) reported that the plant at Billingham for coal-hydrogenation is now working and will, when at full output, produce 45,000,000 gallons of motor spirit yearly—3¾ per cent of our annual consumption. By August, the total production —including that from distillation of oil shale and coal—will reach 60,000,000 gallons, increasing to 90,000,000 gallons when the Billingham plant attains full output. Although petroleum can be got from the earth for relatively slight efforts, one of the chief merits claimed for coal-hydrogenation is the magnitude of the labour it requires and the employment it gives. This, however, is small in comparison with the size of the coal industry. The present Billingham output employs 1,900 miners and 1,000 plant employees, and it does not seem probable that the process can restore the former prosperity of the mining industry. Capt. Crookshank also stated that 43 applications had been received to prospect and work for oil in Great Britain.

Mr. Lloyd George's Scheme of National Reconstruction

MR. LLOYD GEORGE'S scheme of national reconstruction is outlined in a pamphlet entitled "Organizing Prosperity" (Ivor Nicholson and Watson. 6*d*.). His main thesis is that our economic system can be amended without being scrapped, and that the immense advantages of individual enterprise, energy and initiative which our present economic system fosters are not to be lightly sacrificed. They must rather be controlled and cultivated so that they may yield an ordered harvest for the nation. He gives first place to the land as a means of finding not only temporary employment during a period of exceptional trade depression, but also permanent employment for our surplus population. Other projects advocated include housing and slum clearance, electrification of suburban railways, improvement of ports and docks, extension and improvement of electrical supply, road developments, water supply, telephone extensions and financial assistance for development of oversea markets. These various schemes would be financed by a 'prosperity loan', while the carrying out of the programme would be entrusted to a National Development Board consisting of a small body of persons of distinguished competence drawn from industry, commerce, finance, workers and consumers who would be appointed for a definite term and would be responsible to the Cabinet. But since a Cabinet of about a score of Departmental Ministers is an unsuitable body to give full and dispassionate consideration to bold schemes of national reconstruction, Mr. Lloyd George advocates a reversion to the War-time arrangement of an executive consisting of the Prime Minister and four or five Ministers without departmental duties.

Science and Vocational Advice

IN a Friday evening discourse delivered at the Royal Institution on May 10, and now available as a pamphlet, Dr. C. S. Myers discussed the "Scientific Approach to Vocational Guidance". He compared the giving of vocational advice with the giving of medical advice. Each is an art, yet each depends on the use of scientific knowledge and methods. The individual must be studied with regard to every relevant aspect of himself and his environment. In vocational guidance, the part played by psychological tests is essential, although relatively small. It is now possible to estimate intelligence fairly accurately, by means of 'verbal' and 'practical' tests, and as the degree of intelligence required varies in different groups of occupations, this is one very important deciding factor. But tests for character and temperamental qualities are not yet sufficiently reliable ; and the chief contribution of the psychologist in this direction has been in the introduction of improved and systematic methods of assessment. Other qualities necessary for success in certain occupations are mechanical ability and manual ability. Tests for these abilities and others, based on a detailed study of some one occupation, can be applied in vocational *selection* where the problem is one of selecting the best person for a particular job. The co-operation of parents, teachers, school authorities and juvenile employment officers provides a necessary contribution to the data on which the vocational adviser's advice is based. The follow up of advised cases, and comparison with the results obtained from a control-group are now recognised parts of the experimental procedure. During the past nine years, the number of cases dealt with in Great Britain by the two bodies responsible for most of such research was 6,751 ; in 1925 the number of vocational guidance cases was less than 100.

T. A. Coward Memorial Sanctuaries

ON July 22, the Earl of Crawford and Balcarres opened the Nature sanctuary at Cotterill Clough.

Cheshire, formed by public subscription in memory of the late T. A. Coward, sometime lecturer in the University of Manchester and author of "The Birds of Cheshire", "The Fauna of Cheshire", etc. The deeds were handed over to the Society for the Promotion of Nature Reserves. The Earl of Stamford, chairman of the memorial committee, said 1,570 people from all parts of the world had subscribed £925 to save this well-known haunt of fauna and flora, and also a second memorial sanctuary at Marbury Mere, and subscriptions coming from so far apart as Canada and Hong-Kong showed the wide appreciation of Mr. Coward's work. The sanctuaries were chosen not only for their own particular appropriateness and value for study, but also because Coward himself studied in them so often. One part of the sanctuary will be permanently closed as a true Nature sanctuary for wild life, but a public right of way will exist at another part where visitors can see down the sanctuary and hear the bird songs. A bronze memorial plaque on a glacial boulder brought from the Bollin Valley is inscribed: "In Memory of Thomas Alfred Coward, M.Sc.,—1867–1933—Cotterill Clough and Marbury Reed Bed were purchased by public subscription to remain for ever undisturbed Nature reserves as a memorial to his great services to natural science". Already studies have been made in the sanctuary by the Manchester branch of the British Empire Naturalists' Association and the Altrincham Natural History Society. The opening ceremony in the Clough was attended by delegates from natural history, scientific, ramblers, and other bodies chiefly from the north of England.

Recent Archæological Discoveries in Crete

OPPORTUNITY for further study of the archæological material found in a cave at Arkalokhori in Crete (see NATURE, July 6, p. 15) has led to some modification of opinion as to its character, though not as to its importance. Sir Arthur Evans, in a communication to *The Times* of July 29, states that as a result of comparative study of the hieroglyphic inscription in three vertical lines on the votive bronze double axe, he has arrived at the conclusion that it does not, as at first supposed, represent an exotic script. He finds that while one or two new forms appear, nearly all the signs have close parallels in the Cretan series, while two recur in the same collocation on a faceted hieroglyphic cylinder in his possession. He is, therefore, of the opinion that the language is identical, though the new inscription, from its associations with material belonging to Late Middle Minoan, must be regarded as late in its class, dating from about 1600 B.C. From one of the lairs of a badger, from which animal the locality takes its name, a fairly complete series of potsherds, covering most of the Minoan periods, was recovered. Sir Arthur, passing on in the same communication to recent work at Knossos, chronicles an exploration of Minoan deposits, in which the most remarkable discovery was a small limestone head. This was of a markedly dolichocephalic early Egyptian type, though associated with relics of the closing Middle Minoan age. Mosaics of Hadrianic age from a villa recently found in the vineyard of the Villa Ariadne, in which the heads of Dionysiac figures in medallions are the recurring subject, have been pronounced to excel any Roman specimens of the kind yet found in Greece.

Origins of Man in America

SEARCH for evidence bearing on the problem of early man in America, which has been carried on in New Mexico during the past five years by Mr. Edgar B. Howard under the auspices of the Academy of Natural Sciences and the University Museum, Philadelphia, is now to be extended farther afield. When it was announced a few years ago that the stone implements of a type hitherto unknown in America, but now known as 'Folsom points', had been discovered near Folsom, New Mexico, by Prof. E. B. Renaud, of the University of Denver, a new orientation was given to the study of American archæology, more especially in the attitude towards alleged associations of artefacts with the bones of extinct or presumedly early fauna. An antiquity for man in America greater than that generally admitted seemed a possibility. Mr. Howard's explorations in New Mexico, of which an account is to appear in the *Museum Journal* (Philadelphia), and especially his discoveries in a cave west of Carlsbad and in old lake beds near Clovis, New Mexico, at a depth of eight feet, of artefacts and traces of camp fires in association with the remains of extinct fauna—camels, wild horse, elephants—indicate that Folsom man had penetrated to the south-west in Pleistocene times, when the Wisconsin ice-sheet was waning, a period of climatic change tentatively fixed at 10,000 years ago. No contemporary human remains have been found. Mr. Howard is of the opinion that further evidence must be sought in Asia, and is now on his way, with the assistance of the Philadelphia Academy of Natural Sciences, to Russia, where he proposes to study the archæology of Siberia and hopes to enlist the co-operation of the Soviet authorities in further exploration. In the meantime, Dr. F. de Laguna, also on behalf of the Philadelphia Academy of Natural Sciences, has resumed her researches in Alaska—on this occasion in the Yukon Valley and with the object of tracking Folsom man on his way to the south-west.

Marriage Hygiene

A NEW quarterly journal, *Marriage Hygiene*, with a strong editorial board consisting, for the time being, of a number of prominent Indian medical men, has recently appeared from the *Times of India* Press, Bombay. Its objects are to secure for the science of conjugal hygiene a proper place in preventive medicine, to publish contributions which are believed to be necessary for scientific, sane sex teaching, and to bind its readers together into a brotherhood of clean thinkers and bold fighters against prejudice and taboos; and it is intended, by additions to the editorial board, that the journal should become an international one. The first number consists of

articles published elsewhere by Havelock Ellis, Julian Huxley, Norman Himes and others, and includes several pages of abstracts and reviews of books. In the second number there is an excellent article by Norman Himes on contraceptive technique in Islam and Europe in the Middle Ages. The articles so far published indicate the scope of the journal and the quality of its contributors. It promises well, and should receive a welcome from all who are interested in those problems which arise from the relation of male to female and of parent to offspring. The price of a volume is 18*s*., and the address of the managing editor is Kodak House, Hornby Road, Bombay. Surely it is a matter of profound significance that such a journal should have had its origin in India, particularly when it is learned that, associated with the journal, there is a eugenic clinic. It would seem that this journal intends to deal frankly and scientifically with a number of topics that are not usually encountered in the ordinary medical journals.

Recent Acquisitions at the British Museum (Natural History)

THE Zoological Department has received, as a donation from His Excellency the Governor of Sierra Leone, the skull and tusks of a young specimen of the forest elephant, from the Gola Forest, Sierra Leone. This specimen is of exceptional importance as it is accompanied by two complete tusks which are in every way similar to the tusks hitherto accepted as belonging to the so-called 'dwarf' elephant. The skull and teeth of this specimen prove it to be quite a young individual and therefore it is reasonable to conclude that the so-called 'dwarf' elephant ivory is merely the ivory of young elephants. 135 mammals, 144 birds, 9 reptiles, and 500 fishes from Ashanti have been collected for the Museum by Mr. Willoughby P. Lowe and Miss Waldron, and about 200 birds collected in southern Asia Minor by Mr. Charles Bird have been purchased. The important collection of British Lepidoptera formed by the late Robert Adkin, who died at Eastbourne on May 21, has been bequeathed to the Department of Entomology. This collection consists, at an estimate, of about 50,000 specimens, and embraces the microlepidoptera as well as the larger kinds to which most collections are confined. The Trustees approved the purchase for the Department of Geology of an important collection of some two thousand Australian fossils, including fishes, representatives of most of the invertebrate groups, and plants. It is particularly valuable on account of the large number of Permian and Triassic insects, including more than 100 types, which it contains. An interesting and valuable gold nugget from Morro Velho, Minas Geraes, Brazil has been bequeathed to the Department of Mineralogy, by the late Mrs. M. A. Bushnan, of Kew. The nugget, which weighs 119·3 grams, or nearly 4 ounces troy, consists entirely of native gold, all the original quartz having been removed, leaving a cellular structure. Among the purchases may be mentioned: a splendid scissor-cut yellow scapolite, weighing 12·3 carats. The rough stone was from Serra da Chibita, Minas Geraes, Brazil. Scapolite of gem quality is not common, and this specimen is larger and of better colour than any other in the National Collection.

A Disease-Resistant Red Currant

A SHORT note issued by Science Service of Washington, D.C., announces the discovery by Dr. G. G. Hahn of a new variety of red currant resistant to the uredo- and teleuto-spore stages of *Cronartium ribicola*, the white pine blister rust fungus. This organism is heterœcious, spending its life-history on two distinct host plants. Currants and gooseberries are the summer hosts, whilst the æcidial stage is spent upon white pine (*Pinus strobus*) in the winter. Many districts in America regard the white pine as their principal source of wealth, and so both wild and cultivated currants and gooseberries were eradicated completely. This caused much grief and expense to gardeners, but removed the necessary summer hosts of the fungus, and effectively controlled the disease on white pine. The new disease-resistant red currant is known as 'Viking'; it provides fruit of good quality, and promises to withstand drought as well as to resist disease.

Centralisation of Scientific Publication

IN an address on "The Dissemination of Science" before the American Association for the Advancement of Science at Minneapolis on June 26, Mr. Watson Davis, director of Science Service, reiterated a plea for the co-operative centralisation of some scientific publication functions in a Scientific Information Institute. It was suggested that manuscripts which could not be published promptly or in full should be sent to the Institute and prepared by typing or otherwise for photographic publication. The existence of the paper or monograph would be made known through the publication of the abstract in the scientific journal, and the paper could be obtained on request, each copy being made to order. The same system could be utilised for supplying to members the scientific papers delivered at a meeting. The photographic procedure might also be utilised for loans between libraries. In regard to bibliography, Mr. Davis suggested the operation by the Scientific Information Institute of a bibliographical file and production service to absorb existing bibliographical schemes in all branches of science and provide bibliographical material in fields of science which are at present not easily accessible. A fund of approximately 20,000 dollars would enable these projects to be initiated.

The National Central Library

THE nineteenth annual report of the National Central Library, Malet Place, London, W.C.1, directs attention to the difficult financial problems which at present confront the Committee. These are due partly to the inadequacy of its income to meet the growing demands made upon the Library and partly to the termination of the annual grants received from the Carnegie Trustees, from whom a final grant of £4,000 has now been received. The annual grant

of £3,000 from the Treasury has again been reduced by 10 per cent, and it has only been possible to spend £2,337 on books, the smallest expenditure for seven years. The financial difficulties are the more unfortunate when the work of the Library in tracing out-of-the-way books and acting as a clearing-house for the entire library system of Great Britain and a chief source of all bibliographical information is becoming more widely known and appreciated. The report contains references to the 'outlier libraries'—which now number 149, including those of a number of research associations, the regional library systems, the university libraries, and the foreign libraries—which will probably surprise the average scientific worker in the extent to which they reveal the co-ordination of effort in this field. Moreover, as the regional system grows, the work represented by each book issued by the Central Library continues to increase, as although the number of books issued may decrease the percentage of books difficult to trace and obtain becomes higher. Of particular interest is work on Union Catalogues, and the Union List of Periodicals in the University Libraries has been of the greatest service in locating periodicals. The report also refers to a Union List of Scientific, Technical and Commercial Periodicals in the Public, the University and all the Technical Libraries in Sheffield. A total of 61,187 books was issued by the National Central Libraries and 11,231 by the outlier libraries, which contain 5,846,000 volumes; 2,409 books were lent to university libraries, 1,233 of which were supplied from the Library's own stock.

Thermo-couple Standardisation

THE use of thermocouples for the measurement of temperature has become so customary in industry that the issue by the Bureau of Standards of the United States of a pamphlet of 36 pages by Messrs. W. F. Roeser and H. T. Wensel on the methods of testing them and the materials of which they are constructed will be welcomed by many workers in industry. It is Research Paper 768 of the Bureau, and is issued at the low price of 5 cents. It deals with the best materials to use for a given range of temperature, how to secure that they are pure and how to standardise the couples when constructed. On the whole, the authors prefer a freezing point rather than a boiling point for a standard temperature when each is available, but instructions are given for carrying out standardisations in each way and also for comparisons with working standards of the thermo-couple type. The best methods of interpolating for temperatures between the standard temperatures are also dealt with. Some idea of the accuracy to be expected from observations with various types of thermo-couples over different ranges of temperature is also given.

The World Power Conference

AT the annual meeting of the International Executive Council of the World Power Conference, held at the Royal Netherlands Institute of Engineers, The Hague, Sir Harold Hartley, chairman of the British National Committee, was elected by the Council as its chairman, in succession to the late Mr. D. N. Dunlop, who died on May 30. The choice of Sir Harold is peculiarly appropriate, since as a vice-president of the London Midland and Scottish Railway Company, and director of research of that great transport system, he is in close touch with industrial problems, while as chairman of the Fuel Research Board and a research fellow of Balliol College, Oxford, he is also conversant with the more academic aspects of scientific progress. The Conference owes to Mr. Dunlop, its founder, a happy combination of the practical with the ideal. Under Sir Harold Hartley's guidance it should continue to progress and to play an increasingly influential rôle throughout the world.

Dovedale

MR. ROBERT MCDOUGALL, of Manchester, has presented to the National Trust further sections of Dovedale. The dale lies partly in Derbyshire and partly in Staffordshire, and it was recently announced in Parliament that steps were being taken by the local authorities concerned for the planning of the whole area. This announcement was warmly welcomed by the National Trust. Now Mr. McDougall has added to his previous gifts 52 acres in Biggin Dale which joins Wolfscote Dale—as the upper part of the Dove valley is called—on the Derbyshire side some way above the land recently given by Imperial Chemical Industries, Ltd. Biggin Dale is a dry limestone gorge of great beauty. The new property, on its north-western side, consists of steep grass slopes with picturesque screes and some timber and hawthorn bushes, and from it there are arresting views down the Dove valley. There are also fine views across to the Staffordshire side of the Dove valley where the Peasland Rocks stand out boldly. Above the property is Wolfscote Hill (1,272 ft.) which, with its long ridge, is a great landmark in the neighbourhood.

Italian Council of Research

THE recent activities of the Italian National Council of Research, which is directed by the Marchese Marconi, are described in an official publication dealing with investigations which the Council has handed over to the universities, higher teaching centres and experimental stations in Italy. During the years 1933 and 1934, researches were carried out in the problems of nutrition in the laboratories and institutes of physiology and biochemistry at Naples, Padua, Genoa and Rome, as well as investigations on the etiology, epidemiology and prophylaxis of typhoid fever in the institutes of hygiene at Bologna and Genoa.

Toxicity of Industrial Solvents

AT the request of the Home Office, the Medical Research Council has undertaken to promote investigation into the question whether various volatile substances might injure the health of workers using them under industrial conditions. The Council has appointed the following special committee to assist and advise in this matter: Sir Joseph Barcroft

(chairman), Mr. J. C. Bridge, Prof. A. J. Clark, Prof. A. G. Green, Prof. J. A. Gunn, Prof. E. H. Kettle, Dr. H. B. Morgan, Mr. J. Davidson Pratt, Mr. D. R. Wilson and Sir David Munro (secretary).

International Office for the Protection of Nature

THE Dutch and French Governments have now officially recognised the International Office for the Protection of Nature at Brussels and have appointed the following delegates to be their representatives on the general council of the Office: *Netherlands and Dutch East Indies:* Dr. P. G. van Tienhoven, president of the Society for Nature Protection in Netherlands; Dr. W. A. J. M. van Waterschoot van der Gracht, chief engineer of mines; Prof. L. Ph. le Cosquino de Bussy, director of the Colonial Institute, Amsterdam; Dr. J. C. Koningsberger, former Minister of Colonies. *France and Colonies:* M. M. Bolle, conservator of forests, Ministry of Agriculture, Paris; Prof. A. Gruvel, general secretary of the National Committee for the Preservation of Fauna and Flora in the Colonies; M. Raoul de Clermont, president of the Section for Nature Protection of the Société Nationale d'Acclimatation de France.

Speleological Research in Great Britain

AT the meeting of representatives of associations interested in the exploration of caves from Yorkshire and Lancashire, Derbyshire and Staffordshire, Somerset and Devon, South Wales and Ireland (see NATURE, July 20, p. 98) held at Derby on July 27, over which Prof. L. S. Palmer (Hull) presided, it was resolved to form a British Speleological Association to serve as a clearing house for the co-ordination of the hydrological, geological, geographical, archæological and biological aspects of cave exploration, and for the dissemination of information relating thereto. In the course of the discussion which preceded the carrying of the resolution, stress was laid on the damage done by promiscuous and uninstructed digging in caves, Mr. A. L. Armstrong (Warrington) in particular urging the need for training before any attempt is made to carry on the work of excavation. The meeting also adopted a proposal that Sir Arthur Keith should be invited to become the first president of the Association.

Awards of the Royal College of Physicians

AT a meeting of the Royal College of Physicians of London held on July 25, the president announced the award of the Baly medal to Dr. F. H. A. Marshall, as a pioneer in the experimental investigation of sex, in physiology and the relation of hormones to [illegible] the award of the Bisset Hawkins medal to [illegible] queathed by Newman, for his distinguished services to [illegible] late Mrs. [illegible]th, and more particularly for the leading [illegible] which weigh by him in the institution of social medical [illegible] consists entire[illegible]erhulme scholarships were awarded to [illegible] having been re[illegible]e and Dr. C. C. Ungley; and a grant [illegible] Among the pur[illegible]nd to Dr. Janet Vaughan to continue [illegible] scissor-cut yellow[illegible] she was engaged before relinquish[illegible] The rough stone wo[illegible]. Dr. E. G. L. Bywaters and [illegible] were re-appointed for six months as Mackenzie Mackinnon scholars. The Murchison scholarship was awarded (by the University of Edinburgh) to W. M. Wilson.

Announcements

THE twelfth International Congress of Zoology will be held at Lisbon in September under the presidency of Prof. Arthur Ricardo Jorge, Jr. Further information can be obtained from the general secretary, Congrès international de Zoologie, Faculté des Sciences, Lisbon.

A CONFERENCE on academic freedom will be held in the University Museum, Oxford, on August 14–15. It will be divided into three sessions, namely: academic and professional freedom; international professional relief; and the utilisation of science. Among the speakers will be Bertrand Russell, G. D. H. Cole, Prof. N. Bentwich, Miss J. Thomas, Prof. H. Levy, L. J. Hodgson. Further information can be obtained from C. R. Morris, Balliol College, Oxford.

THE tenth and eleventh reports of the Committee on Contact Catalysis, Division of Chemistry and Chemical Technology, have been issued together by the National Research Council, Washington. They deal with general aspects of catalysis, activated adsorption, the nature of chemical binding, interchange of energy in molecular collisions, chain reactions and some technical applications of catalysts.

APPLICATIONS are invited for the following appointments, on on before the dates mentioned:

A temporary assistant lecturer in applied mathematics in the University of Liverpool—Registrar (Aug. 10).

A biochemist (part-time) for the Pathological Department, Manchester Northern Hospital—The Secretary, J. C. Daniels, 38 Barton Arcade, Manchester (Aug. 10).

A lecturer in botany in the United College, St. Andrews—Secretary and Registrar (Aug. 10).

An assistant (Grade III) and a temporary assistant (Grade II) in the Admiralty Compass Department, Slough—Secretary of the Admiralty (C.E. Branch), London, S.W.1 (Aug. 10).

A veterinary research officer to the Government of Burma—The High Commissioner for India, General Department, India House, Aldwych, London, W.C.2 (Aug. 14).

An assistant lecturer and demonstrator in engineering in University College, Cardiff—The Registrar (Aug. 19).

Two assistant keepers at the Victoria and Albert Museum—Director and Secretary, South Kensington, London, S.W.7, marked "Assistant Keeper" (Aug. 31).

City microbiologist to the Municipal Council, Colombo, Ceylon (candidates to be from the United Kingdom)—Messrs. John Pook and Co., 68 Fenchurch Street, London, E.C.3 (Sept. 30).

A lecturer in geography and mathematics in St. Hild's College, Durham—The Principal.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 187.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

The Fundamental Paradox of the Quantum Theory

UNDER the above title, Prof. G. Temple[1] deduces the paradox from the general principles of the quantum theory, that any two operators representing physical variables must commute. If this conclusion be correct, it would involve fatal consequences; therefore we should like to point out that the commutability of operators does not follow from the general principles, but only from the particular and rather arbitrary principle of symmetrisation, which Prof. Temple claims to have deduced, but which is a new hypothesis in reality.

It is generally accepted that "physical variables a, b, c, . . . are represented by symmetric linear operators A, B, C, . . . in Hilbertian space; and the representation satisfies the following conditions:

$$a^2 \rightarrow A^2,\ \lambda a \rightarrow \lambda A \ (\lambda \text{ being an ordinary number})$$
$$a + b \rightarrow A + B."$$

Furthermore, it is also admissible to conclude from the relation $ab = \frac{1}{2}(a+b)^2 - \frac{1}{2}(a-b)^2$, which is also a c-number relation, that $ab \rightarrow \frac{1}{2}(AB + BA)$. This way of symmetrisation is unique, if products of only two physical variables are considered. In the case, however, of using products of more than two physical variables, this symmetrisation can no longer be derived uniquely from a c-relation. For then it is possible to convert artificially the case of two variables into the case of three variables, having then several possibilities of symmetrisation.

We put, for example, $A = (FF^{-1}).A$, where F is an operator and F^{-1} its reciprocal. Assigning $F^{-1}A = D$, then evidently $ab = fdb$.

According to Temple's symmetrisation

$$fd.b \rightarrow \tfrac{1}{4}(FD + DF)B + \tfrac{1}{4}B(FD + DF).$$

Here, and in the general case of three variables, we will choose, however, in a more symmetrical way the sum of all six permutations of the three variables.

All the different possibilities of symmetrisation give the same result only then, if the variables commute. Hence we cannot conclude that all variables must commute because a special prescription of symmetrisation does not exist in quantum mechanics.

Note added in proof.—Further consideration shows that, starting from the above representation of physical variables by linear operators as assumed by Prof. Temple, the correct symmetrisation of products of physical variables should be made by forming the sum of all the permutations of the variables.

A detailed report on the question of symmetrisation will be published later.

H. FRÖHLICH.
E. GUTH.

Institut für theoretische Physik,
Universität,
Wien.
June 15.

[1] G. Temple, NATURE, 135, 957, June 8, 1935.

To remove any possible misunderstanding, let me say explicitly that the argument of my previous letter was not intended as a serious demonstration that any two operators representing physical variables must commute, but as a definite proof of the existence of some serious and fundamental defect in the form of modern quantum theory. The criticisms to which the argument has been subjected have concerned either the conditions which were assumed to be satisfied by the representation of variables by operators, or the method by which the representation of a triple product was obtained.

With regard to the first group of criticisms, it is sufficient to reply that the assumed conditions are universally accepted, and that the denial of any one of them is as fatally destructive of the present form of the quantum theory as is the acceptance of the commutability of any pair of physical operators. To say that the same variable need not always be represented by the same operator renders it impossible to interpret any operational formula: to deny that $a + b \rightarrow A + B$, unless A and B commute, makes it impossible to construct any Hamiltonian operator as the sum of the operators representing the kinetic and potential energies: to deny that $a^2 \rightarrow A^2$ invalidates the whole theory of the momentum operators.

Criticisms of the second kind have usually taken the form of the assertion that the operator representing abc is

$$\tfrac{1}{24}\{(A+B+C)^3 - (-A+B+C)^3 - (A-B+C)^3 - (A+B-C)^3\},$$
$$\equiv \tfrac{1}{6}(ABC + BCA + CAB + CBA + ACB + BAC).$$

Certainly, this is *a* legitimate deduction from the premises, but it is not the *only* possible deduction. I agree with Messrs. Fröhlich and Guth that in the case of triple products a unique form of the representation cannot be derived from c-relations between variables. But I deny that I have employed a "particular and rather arbitrary principle of symmetrisation . . . which is a new hypothesis in reality". I have based my deduction on the three premises admitted by Messrs. Fröhlich and Guth, and I challenge them to point out at what stage in my argument any further assumption has been made. Any triple product abc is also a double product of a and bc, or of b and ca, or of c and ab, and its representations are therefore deducible by the recognised rule for all double products, that is, that

$$xy \rightarrow \tfrac{1}{2}(XY + YX).$$

This is the gist of my argument, and *qua* argument it is invulnerable.

What, then, is the origin of the paradox? It can only arise from the fundamental concept of the representation of the variables of classical physics by the operators of quantum theory. The assertion that such a representation exists is the form taken

by the Correspondence Principle in modern quantum theory, and the paradox to which I have directed attention is a definite proof that, in this form, the Correspondence Principle is false. It is false for the obvious reasons that physical characteristics cannot be simultaneously describable by classical variables and by quantum operators, and hence that there cannot be any rigorous one–one correspondence between these two systems. Trivial though this conclusion appears, it is sufficient to require the complete revision of the greater part of the quantum theory, which at present still leans heavily on the crutches of the Correspondence Principle.

Isotopic Constitution of Uranium

THE analysis of uranium rays from the volatile hexafluoride by Dr. Aston[1] has shown a single line at atomic weight 238. The element appeared to be simple to at least two or three per cent, but its properties were not favourable for study in the gas discharge. As uranium is of great importance for the subject of radioactivity, the spark source described in NATURE of April 6 (135, 542) was tried with uranium metal and gold as electrodes, and also with an electrode made by packing a nickel tube with pitchblende. It was found that an exposure of a few seconds was sufficient for the main component at 238 reported by Dr. Aston; but in addition on long exposures a faint companion of atomic weight 235 was also present. With two different uranium electrodes it was observed on eight photographs, and two photographs with the pitchblende electrode also showed the new component. The relative intensity could be only roughly estimated on account of the irregularity of the spark, but it appeared to be less than one per cent of the intensity of the main component.

This faint isotope of uranium is of special interest as it is in all probability the parent of the actinium series of radioactive elements. In discussing Dr. Aston's analysis[2] of the isotopes in lead from radioactive minerals, Lord Rutherford[3] pointed out that the lead isotope of atomic weight 207 is probably the end product of the actinium series, so that the atomic weight of protoactinium would be 231, $(207+6\times4)$. This value has been verified by the recent chemical determination of the atomic weight by v. Grosse[4]. Protoactinium itself may be formed by α- and β-ray transformations from a hypothetical isotope of uranium, actino-uranium, with an atomic weight of 235 or 239[3]. The relative amount of actino-uranium at present on the earth would be 0·4 per cent of the uranium according to a recalculation by Dr. v. Grosse[5,6]. The present observations thus support this theory, with the atomic weight of 235 for the isotope actino-uranium. A third isotope, uranium II, of atomic weight 234 amounts theoretically to only 0·008 per cent of the uranium, and would be too faint for observation by the mass-spectrograph.

Intensity of Polarised X-Rays

To obtain a pencil of plane-polarised X-rays as free as possible from unpolarised radiation, Barkla's original method is still the standard. The resulting beam produced by scattering an ordinary X-ray beam through 90° from its original direction is always very weak. Partial polarisation of the direct beam from an X-ray tube was found by Barkla, and Kulenkampff[1] found strong polarisation near the short wave-length limit in the general radiation. Mark and Szilard[2] found no polarisation in the fluorescent radiation even at 90°. In the scattering method some increase of intensity is found when the scatterer will give a 'powder' line for which the Bragg angle, for the strongest component of the incident radiation, is 45°.

The polarised beam got by any of these methods proved too weak for use in some experiments on the interaction of polarised X-rays and crystals. A serviceable polariser for CuK_α radiation was made by using a single crystal as the scatterer. The most intense beam was got from a single crystal of copper cut parallel to the 311 planes ($2\theta = 90°\ 10'$). Serious reduction in reflecting efficiency due to distortion can be avoided by the use of a special technique for preparing the section. The results of a comparison of intensity of the beam of polarised X-rays given by such a polariser and by the standard methods are shown in the table. As an ionisation spectrometer was not available, a photographic method had to be used. An attempt was made to produce the same blackening of photographic film by each of the methods in turn under similar conditions of working of the X-ray tube and of photographic development. Each film was then measured on a Moll microphotometer and the blackening expressed as $\log_{10}(I_0/I)$, where I_0 is the galvanometer deflection when the unblackened film is before the thermopile and I is the corresponding deflection for the blackened film. The value 0·301 is for a film transmitting one half of the light incident upon it normally.

Scatterer	Density of blackening of film	Time of exposure (sec.)
Section of single crystal of copper	0·441	5
Copper powder (foil)	0·301	900
Carbon block	0·344	3,600
Wax block	0·414	4,800

Since photographic blackening by X-rays is a function of the product of the incident X-ray intensity and the time of exposure[3], the results show that the increased efficiency got by using the single crystal polariser is of the order 100 to 1000 fold. Since the polarised beam from the crystal is a directed beam, greater accuracy of setting of the apparatus is needed than for the standard methods, but the routine accuracy of X-ray crystallography suffices. With this more powerful beam, advantage can be taken, in the study of the interaction of X-rays and matter, of the vectorial properties of polarised X-rays. In one such experiment now in progress it was found that an exposure of 24 hours was necessary with polarised X-rays when an exposure of 5 min. with ordinary X-rays sufficed. Without the thousand-fold increase of efficiency the experiment was impracticable, needing apparently an exposure of nearly three years.

Extreme Infra-Red Absorption of D_2O, Ice and D_2O in Dioxane

THE broad absorption band observed in liquid water at about 160 cm.$^{-1}$ might be attributed to a free rotation of individual molecules, a combination frequency of near infra-red bands, or to a quasi-crystalline structure. The difference between the absorption of H_2O in the liquid and vapour states suggests the latter, and we can attribute it to either (1) hindered rotation or (2) hindered translation. This frequency being strongly infra-red active I interpreted it as due to a hindered rotation of the molecules[1]. Bernal and Tamm[2], using the model described by Bernal and Fowler[3], predict a fundamental frequency of hindered translation near 160 cm.$^{-1}$ and a fundamental frequency of hindered rotation at 480 cm.$^{-1}$. Measurements on D_2O permit us to decide between phenomena (1) and (2): for hindered rotation the frequency should be shifted by $\sqrt{2}$, for hindered translation by $\sqrt{20/18}$, or about 5 per cent.

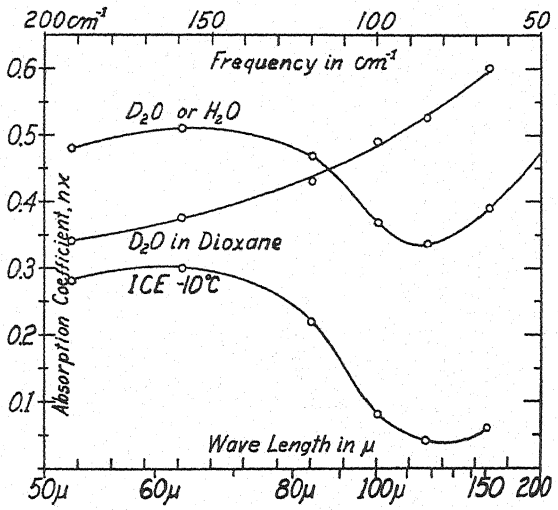

FIG. 1.

Within our experimental limits, D_2O and H_2O had the same absorption between 60 cm.$^{-1}$ and 200 cm.$^{-1}$. The absorption band near 160 cm.$^{-1}$ can therefore be assigned to a hindered translational frequency of D_2O or H_2O molecules as predicted by Bernal and Tamm. However, if this frequency were due only to a vibration of water molecules in a quasi-crystalline structure, it should be neither infra-red active nor Raman active. The difficulty might possibly be removed (using the model proposed by Bernal and Fowler[3]) by assuming that some of the four surrounding molecules are forced to follow the vibrations of the molecule at the centre by turning. This could in effect make a hindered translational motion infra-red active and also weakly Raman active, as is observed[4, 5].

The existence of the 160 cm.$^{-1}$ band in ice at − 10° C., as shown in Fig. 1, is additional evidence for a quasi-crystalline structure in water, and indicates that the intermolecular forces are about the same in water and ice. As is also shown in Fig. 1, the 160 cm.$^{-1}$ band disappears for water dissolved in dioxane, which confirms that its presence was due to a structure in water rather than to the individual molecules. The absorption of dioxane has been subtracted in calculating the curve in Fig. 1.

Bolla[4] reports a feeble Raman band near 60 cm.$^{-1}$. If this frequency is infra-red active, it is masked by the absorption due to the orientation of the permanent dipoles, as is best seen for water dissolved in dioxane. The absorption coefficient of water increases[6] to a maximum of 2·7 at 0·6 cm.$^{-1}$.

Absorption measurements of the hindered rotation band predicted by Bernal and Tamm[2] at 480 cm.$^{-1}$ would be experimentally difficult, but the measurements of the reflecting power[7] show a distinct maximum about 500 cm.$^{-1}$ (much stronger than that for the 160 cm.$^{-1}$ band). This frequency, if it were due to a hindered rotation, should indeed be strongly infra-red active; however, an accompanying distortion of the configuration of the surrounding water molecules seems necessary to explain the feeble Raman band observed in this region[4, 5].

I wish to thank Prof. E. K. Rideal for kindly supplying the D_2O used in these experiments.

Molecular Polarisation of Solutes and Dielectric Constant of Solvents

EXPERIMENTALLY it is indicated that the different total polarisations shown by the same solute when dissolved in different solvents are to be related to alterations in the orientation polarisations ($_0P$) caused by replacement of one dielectric environment by another, the atomic and electronic polarisations being constant throughout such changes. Therefore the expression given by Raman and Krishnan[1] for the volume polarisation of a dielectric, namely:

$$\frac{\varepsilon - 1}{\varepsilon + 2} = \nu\left(\frac{4\pi}{3}\frac{\alpha_1 + \alpha_2 + \alpha_3}{3} + \frac{\varepsilon - 1}{\varepsilon + 2}\psi\right) + \frac{\nu}{3kT}\left(\frac{4\pi}{3}\mu^2 + \frac{\varepsilon - 1}{\varepsilon - 2}\Theta\right)$$

(cf. reference for definition of symbols) can be rewritten to show the molecular orientation polarisation ($_0P_{\text{sol.}}$) of a polar solute at infinite dilution in a non-polar medium of dielectric constant ε as:

$$_0P_{\text{sol.}} = \frac{N}{3kT}\left(\frac{4\pi}{3}\mu^2 + \frac{\varepsilon - 1}{\varepsilon + 2}\Theta\right).$$

Now, dividing throughout by the true orientation polarisation as observed in the gaseous state ($_0P_{\text{gas}} = 4\pi N\mu^2/9kT$) we have

$$_0P_{\text{sol.}}/_0P_{\text{gas}} = 1 + 3\,\Theta/4\pi\mu^2\,\frac{\varepsilon - 1}{\varepsilon + 2}.$$

We wish to direct attention to two points of interest which arise from this result:

(1) The sign of Θ being inversely that of the Kerr constant for the substance, this quantity is for most substances negative, and therefore their polarisations in solution should be, and in many instances have

been found to be, *less* than in the vapour states. Further, in many cases Θ can be considered as approximately equal to $-4/3.\pi.\mu^2$, whence, by substitution,

$$ {}_0P_{\text{sol.}}/{}_0P_{\text{gas}} = 1 + \frac{1-\varepsilon}{\varepsilon+2} = 3/(\varepsilon+2), $$

which is identical with the purely empirical result discussed and illustrated previously[4].

(2) The minority of compounds—for example, chloroform, ether and certain amines—which have negative Kerr constants[3], are particularly significant because *they should exhibit larger polarisations in the dissolved than in the gaseous condition.* Such experimental evidence as is available (cf. ref. 2) appears to support this. One extreme case can be quoted as an example: chloroform (Kerr[3] $B = -3 \times 10^{-7}$) at 25° has an apparent orientation polarisation in the liquid (bulk) state of 23·7 c.c. whilst the highest recorded value in the vapour state, calculated from the results of Sircar[2], is only 22·8 c.c.

Fuller information regarding the orientation polarisations in the gas phase of substances with negative Kerr constants is eminently desirable at the present time.

Coalescence in Stages between Two Drops of a Liquid

A drop of benzene introduced into a vessel of water through a capillary tube spreads to a limited extent over the surface of galena that has been coated by any of the compounds known in flotation as collectors[1]. If now the tube be raised slowly, the benzene drop becomes elongated and then ruptures. The angle of contact being greater than 90°, a portion of the benzene remains on the mineral surface, the greater part contracts into a nearly spherical pendent drop at the end of the capillary tube, and the small portion that formed the 'waist' before breaking becomes a minute drop that rises slowly through the water. It does not immediately coalesce with the pendent drop when they meet. After a variable induction period, a very rapid change occurs, as the result of which the small drop may disappear altogether or may merely decrease in size. On occasions there may be four such diminutions in size before the drop disappears, the induction period for each being several seconds. Other organic liquids behave similarly.

A similar phenomenon has been observed with water. Small drops directed obliquely on to the surface of tap water do not immediately coalesce with it. It is presumed that the surfaces are contaminated by a thin film of grease or dust. Again, coalescence sometimes occurs in stages.

The probable explanation of these facts is that when true contact first establishes itself between the liquid in the small drop and that in the larger surface, spreading occurs so rapidly that the bubble does not fall (or rise) so quickly as its contents drain away; a waist is formed and rupture occurs before the complete drop has been absorbed. It is suggested that these phenomena would repay investigation in a laboratory equipped with a high-speed cinematograph.

Statistical Tests

In discussions on statistical tests with various Continental statisticians and users of statistical methods, I have been struck by their universal mistrust of modern statistical tests as developed by Pearson, Fisher and other workers in Great Britain. I have come to the conclusion that the main reason for this attitude is a perfectly sound reason, namely, that a test is used by many workers in Great Britain as a *simultaneous test* of the untruth of one hypothesis and the truth of the reverse hypothesis. There is *in fact* a large region in the distribution of the criterion for which neither a hypothesis nor its reverse can be assumed to be true. One or the other *is* true, of course, but the test cannot help us in coming to a decision on the matter. Judgment must be reserved. For example, we may wish to test whether a given sample differs significantly from a random sample from a normal population. Applying the χ^2 test, after finding the best fitting normal distribution, and using $p = 0{\cdot}05$, say, as the level of significance, we may find that our sample is just not significantly abnormal.

The χ^2 criterion is perfectly justifiable up to this point. It is quite unjustifiable, however, to assert that the reverse hypothesis is true, namely, that the sample *is likely* to have come from a normal population, unless we have other reasons to believe this, in which case, of course, the χ^2 test is not used as a criterion of the truth of the reverse hypothesis. Given an equal *possibility* of an infinite variety of populations, the most likely group of distributions to have given it contains all those which will give the *modal* χ^2 value for the appropriate number of degrees of freedom. All these and an infinite number of others may be considered as *likely* to have given the sample, compared to the best-fitting normal distribution, which has indeed comparatively a very small likelihood. This likelihood is sufficient, however, to prevent our assuming abnormal distribution.

It is often of scientific and practical interest to investigate whether Gauss's law or other simple laws of distribution apply to a sample. There is no doubt that the χ^2 test, as usually applied, is quite useless for this purpose, though it may be most useful as a test of *significant heterogeneity*, using a low value of P as a criterion. It seems only reasonable that but a small part of the centre of the χ^2 distribution should be used as a test of *fit*.

I believe the mistrust of British methods on the part of the statisticians of other countries to be due partly to their failure to realise that the word 'normal' is usually employed to cover samples which are likely to have arisen from populations the estimates of the mean and other parameters of which have distribu-

tions very similar to those of the corresponding normal parameters. The fact that British methods 'work' is due to the prevalence in Nature of distributions *similar* to the Gaussian rather than to any peculiar virtue in the methods themselves. I am writing this in the hope that some statistician of international repute will be tempted to treat the matter fully in some publication such as NATURE available to statisticians of all countries.

Philosophy and Modern Science

I DO not know whether in a brief compass I can say anything useful in regard to Dr. Jeffreys's letter in NATURE of July 20. Yet it seems a pity that the cardinal psychological distinction upon which I was laying stress[1] should be obscured by mere misapprehension and confusion.

I thought I had made sufficiently clear what I meant by the term *sensum*, namely, *that which is sensed or perceived*, in contradistinction to the *sensing* or *perceiving*. I was not in the least concerned with Russell's theory of sense-data, or as to whether most of what Russell called sense-data are or are not perceived. All I desired to insist upon was that sensing or perceiving is not identical with that which is thereby sensed or perceived. Dr. Jeffreys now tells us that what he means by sensations are such things as various patches of different shapes and colours of which he is aware when his eyes are open, and which disappear when his eyes are closed. Precisely; he is using the term sensation, as I suspected, for that which is sensed, and is ignoring, although all the while assuming (in speaking, namely, of being aware), a process of sensing.

He now maintains that sensations, so understood, seem to be immediate and not to be the result of activity on the part of the conscious subject. With the latter part of this statement I thoroughly concur; but when I am further told that sensations, or sensa, "just happen", I feel bewildered. Surely, patches of various shapes and colours do not "happen"; they simply are; what "happens" is the state or condition of being aware of them. The latter is the mental act; and it is, of course, wholly different from a bodily activity, such as that of "opening my eyes". Whether there be any process rightly describable as "merely having a sensation" is more than doubtful; but most certainly if there is, it is a case of mental activity. Not even the crudest, the most indefinite, *awareness* of a sensuous content is conceivable which does not involve the functions of discriminating and comparing, which functions, as the result of development, ultimately assume the highly evolved form of mental activity we call thinking.

Again, the statement in my letter that a concept, psychologically considered, is a way in which universals are cognised presupposes by no manner of means the existence of universals. We cognise numerous entities—numbers, for example—which are not existents. Indeed, the point I was urging was that an individual existent, such as the planet Neptune, is obviously neither a universal nor a concept. Dr. Jeffreys now informs us, "It is only when many observations are available that we can form the idea of a single body moving in a definite way; generalisation has already been applied in thinking of Neptune at all". Quite true; but what has that to do with the matter? Generalising is, in fact, involved in every act of mature perception, in my perception, for example, of the table at present in front of me; but it does not follow that the object perceived is, on that account, itself a generalisation. Dr. Jeffreys further informs us that what he calls a percept is substantially what Pearson called a construct. Well, I suppose a writer is at liberty to use a term in any sense he chooses. But it is, to say the least, unfortunate when a term with a well-recognised connotation is employed in a manner altogether contrary to its ordinary meaning. Even in popular language, the term 'concept', according to the "Oxford Dictionary", signifies "idea of a class of objects, general notion". The "idea of a single body moving in a definite way" is doubtless an idea of a highly complex object; but it is not, as such, an idea of a class of objects.

The Carr and Price Reaction of the Fatty Acids of Cod Liver Oil after Vigorous Saponification

IT has been demonstrated[1–5] that prolonged and vigorous saponification of the mixed free acids of fish-liver oils causes remarkable changes in their chemical structure and in the absorption in the ultra-violet. When saponifying the acids of cod liver oil in this way, I observed a remarkable change in the Carr and Price reaction of these acids.

Cod liver oil was saponified for 10 minutes with ethyl alcoholic potash, and the unsaponifiable fraction extracted with ether. The fatty acids were distilled (at 0·2 mm.). They were pale yellow in colour and gave with antimony trichloride in chloroform only a yellow colour. The acids were saponified for six hours in nitrogen under reflux with an excess of amyl alcoholic potash. (The amyl alcohol was previously distilled over potash.)

The regenerated acids gave with the Carr and Price reagent a relatively strong and rapidly decreasing violet colour with absorption at 600–620 mμ and at 530–550 mμ. Measured with the Lovibond tintometer, these acids contained per c.c. 300 L.U. (Wolff) = blue value 60. The cod liver oil itself contained 70 L.U. (Wolff) = blue value 14. The substance responsible for the reaction was purified by dissolving the acids in light petroleum and filtering through a Tswett column with activated aluminium oxide. A yellow coloured zone was visible at the top, unaltered even after washing with ethyl alcohol. The pigment was eluted with dilute ethyl alcoholic potash, regenerated by acidification and taken up in ether. After evaporation *in vacuo*, a pale brown-coloured semi-solid substance was obtained. Addition of light petroleum caused a yellow precipitate and removed soluble substances, which gave a reddish brown Carr and Price reaction. The precipitate was washed several times with light petroleum and dissolved in a small quantity of acetone or chloroform. So a colourless impurity which is insoluble in acetone and chloroform could be removed. After evaporation and drying *in vacuo*, a yellow amorphous powder was obtained.

The substance possessed acid properties, a dilute solution in chloroform was yellowish green-coloured and showed by itself no definite absorption bands (absorption from ± 470 mμ down to the lower part of the spectrum). With the Carr and Price reagent a violet colour developed with absorption bands at 525–535 mμ and at 590–620 mμ. The 525–535 mμ band rapidly decreased, the reaction mixture turned blue to greenish blue and a band at 670–690 mμ became visible. The bands at 590–620 mμ and at 670–690 mμ and also the blue colour are relatively stable. The Lovibond value of the yellow substance was 75,000 (Wolff) or blue value 15,000. From 15 gm. of fatty acids a few milligrams of the yellow product were obtained.

Different samples of cod liver oil and halibut liver oil acids showed this reaction with the antimony trichloride reagent. It was not observed with the acids of butter fat or arachis oil, or with carotene, cholesterol or ergosterol.

Further investigations are in progress.

The Metabolism of Retina

SIGNIFICANT differences of the *normal* metabolism of tissues either in Ringer bicarbonate or in phosphate solution have so far not been reported[1,2]. On the other hand, the contradictory results obtained by Dixon and Elliot[3] and Alt[4] respectively concerning the hydrogen cyanide stable residue of the respiration of liver slices have been explained by the use of different media. Nearly complete inhibition occurs in Ringer bicarbonate while a considerable residue remains in phosphate solution or in Ringer without bicarbonate.

The study of the metabolism of retina and tumours has shown the following results:

The respiration of rat's retina and Crocker mouse-sarcoma 189 in bicarbonate Ringer is about twice as high as in phosphate Ringer.

Q_{O_2}

	in bicarb.	in phosphate
Retina	32	17·5
Tumour	12–18	6–9

While the respiration of the tumour is inhibited in both media by about 90 per cent by hydrogen cyanide $n/1{,}000$–$n/500$, *the respiration of retina is inhibited* by

Retina, hydrogen cyanide $n/1000$

	Q_{O_2}	$Q_M^{O_2}$	$Q_M^{N_2}$
Bicarb.	32–35	88	88
Phosphate	3	—	—

the same hydrogen cyanide concentrations *only in phosphate Ringer* but *not inhibited at all in bicarbonate Ringer*. The Pasteur reaction in this case is completely inhibited, the ærobic glycolysis becomes equal to the anærobic. Hydrogen cyanide, therefore, in bicarbonate media acts on retina as ethylcarbylamine[5] on other glycolysing tissues. The anærobic glycolysis is not affected. The inhibiting effect of phosphate and of hydrogen cyanide in phosphate on the respiration is reversible.

The natural thickness of the retina allows the measurement of its respiration at very low oxygen tensions. In nitrogen with 5 per cent oxygen, the respiration in phosphate remains still normal ($Q_{O_2} = 17{\cdot}5$) and under our experimental conditions 95 per cent carbon monoxide with 5 per cent oxygen leads to no inhibition of the respiration of the retina.

Coagulation of the Blood as a Chain Reaction

WITH reference to the letter of Dr. Albert Fischer published in NATURE of June 29 (135, 1075), readers of this journal may be interested to be reminded of the following quotation from a paper by C. Delezenne, published in *Ann. de Physiol. et de Physicochim. biologique* (2, 537; 1926):

"Outre la faculté essentielle qui le définit, le fibrinferment possède encore la curieuse propriété, découverte par BORDET et GENGOU, de faire lui-même naître le fibrinferment, ou tout au moins d'en accélérer considérablement la production, lorsqu'on l'ajoute à un milieu qui en renferme tous les générateurs."

This sentence and what follows it fully substantiate the theory of blood coagulation as a chain-reaction described by Dr. Fischer.

Fish and Rabbit Liver Glycogens

LIVER glycogen from fish of the genus *Gadidæ*, first isolated and described by Bell and Young[1], was subjected to methylation by the procedure of Haworth and Percival[2]. The product showed a methoxyl content of 45·5 per cent (maximum) and was identical with the corresponding derivative from highly purified rabbit liver glycogen in all its properties including $[\alpha]_D$ in water +208° and in chloroform +209°. Hydrolysis with a mixture of aqueous hydrochloric and acetic acids, followed by separation of the cleavage products, yielded an amount of analytically pure tetramethylglucopyranose corresponding to 9·1 per cent of the starting material, while control experiments on methylated rabbit liver glycogen gave 9·5 per cent. Both these values correspond to a molecular magnitude of 12 glucose units for the glycogen molecule, and are in agreement with the findings of Haworth and Percival for commercial rabbit liver glycogen. The methylated glycogens are

further identical with respect to the colour developed with iodine, a deep red-brown, although, as Bell and Young found, the parent substances differ in this respect.

Results recently obtained by Bell and Kosterlitz[3] reveal further identity by examination of acylated derivatives of the two glycogens, and of the glycogens regenerated from these derivatives. It is therefore concluded that fish and rabbit liver glycogens are very probably chemically identical.

These results will be communicated fully through the usual channels.

Homology of the Female Periurethral Glands and the Prostate

So early as 1853, Virchov assumed, on the evidence of histological similarity, that the minute periurethral glands, found in the human female in the neighbourhood of the urethra, are homologues of the male prostate.

The following experiments made by us give experimental confirmation of this and some similar observations, and of the homology of the periurethral glands in the female rat with the ventral lobe of male prostate. The diol of androsterone ($C_{19}H_{32}O_2$, a derivative of male sexual hormone) prepared by Ruzicka was injected into ovariectomised rats for three weeks in doses of 175–700 γ a day. On dissecting the vagina and uterus of these rats, glands, not normally seen in the rat, were found on the vagina, at the base and in front of the bladder. Macroscopically, these glands had the appearance of the ventral lobe of the male prostate. The largest gland measured 6 mm. × 4·2 mm. × 2·2 mm. The addition of œstrone to diol injections did not prevent the development of the 'female prostate'. Microscopical examination revealed a structure typical of the normal ventral lobe of the prostate of the male. This glandular tissue was found in some of the normal and ovariectomised uninjected rats, but only on histological examination; it was in a rudimentary condition, with atrophic cells.

Thus the name 'female prostatic gland' could be used instead of 'female periurethral glands', in order to emphasise the homology of these glands in the male and female, in the same way as the name 'utriculus masculinus' is used to show that this gland is homologous with the uterus of the female.

Depigmentation, a new Dietary Deficiency Disease, cured by Copper

IN a preliminary communication[1] a short description and two figures were given of a peculiar deficiency disease, involving depigmentation and occurring in young, pigmented rats. The only author who has, so far as I know, published a description of the same manifestations in rats, is Hartwell[2]. She attributed these symptoms to deficiency of tryptophane and tyrosine in the diet.

Hitherto I have succeeded in producing a similar syndrome in young as well as in adult rats, young cats and young or adult rabbits. In my opinion, young rats are most susceptible to depigmentation; furthermore, they are susceptible during the whole year. Hartwell, however, could not produce depigmentation in rats during the winter season.

The influence of the feeding of many vitamins and minerals (Cu, Fe, Mn, Zn, Co, Ni, Na, K, Ca, Mg, F, Cl, I, P, S) was tested, separately and together: copper appeared to be the only active principle required for prevention or cure. The dosage must be much higher than for cure of anæmia, namely, 0·02–0·12 mgm. per diem for prevention, and 0·07–0·24 mgm. per diem for cure of the depigmentation. The minimum dosage required may thus vary considerably within these limits, in consequence of its availability and of the anti-copper effect of certain (growth-promoting) food-factors, which should always be present to some extent in a satisfactory diet.

Growth in itself may also promote depigmentation.

Loss of fur bears no relation whatever to the onset of depigmentation. It is cured by entirely different dietary factors (vitamin B_2 complex, cystine, residue factor of yeast or liver) and does not occur in rats fed on rations which are deficient in copper only. On the other hand, bald and depigmented rats may be cured by addition of copper so far as their colour is concerned, and the bald areas do not recover in this way.

Vitamin C in Lower Organisms

THE vitamin C staining reagent (acetic acid – silver nitrate) has been applied to certain protozoa, bacteria, moulds, lichens and algæ.

Various ciliates and *Chlamydomonas* were concentrated by centrifuging, washed with distilled water, and then fixed with the acetic acid silver nitrate solution of Giroud and Leblond. Sections of these protista showed the presence of small black granules scattered in the cytoplasm without exhibiting any association with formed elements of the cell, such as the nucleus, chloroplasts, etc. The granules were rounded and each one was approximately one fifth the size of a single chloroplast in *Chlamydomonas*. Five or six granules occurred in each individual, both *Chlamydomonas* and the ciliates. In some of the latter, it was noticed that there was a tendency for the granules to aggregate round certain vacuoles. The culture medium in which these organisms had grown was tested with the indophenol reagent to ascertain whether vitamin C was being synthesised and excreted by them. No appreciable quantity of vitamin C either in the reduced or in the reversibly oxidised condition could be detected, however, in the medium.

Of the large numbers of *Bacillus coli communis* to which the vitamin C reagent was applied, a considerable percentage showed the presence of a single black granule at one end. No specimens were seen which showed more than one granule. Specimens

of *Mucor* and the blue-green mould *Penicilium* were also examined using the same solution for impregnation, and black granules were found in the mycelium and in the spores. The protoplasm in various types of Algæ, for example, *Spirogyra* (Chlorophyceæ) and *Oscillatoria* (Cyanophyceæ) was seen to contain varying numbers of fine granules. In *Oscillatoria* at the growing tip the granules were orientated in lines radiating backwards from the tip. The granules in the segments farther back were scattered irregularly in the centre of the segment. In specimens of lichen examined, the algal cells contained only a few granules, but the fungal element of the lichen possessed a greater number of granules, aggregated chiefly in the centre of the hyphæ.

It is apparent, then, that in these lower forms of life there is a substance capable of reducing a reagent which in higher forms of life is specific for vitamin C. It is suggested, therefore, that this reducing substance in these lower organisms is vitamin C, in which case it may be that the very existence of living protoplasm is dependent upon the presence of this vitamin. It has been shown in Eutherian mammals, and more recently in the marsupials also, that vitamin C occurs in all the organs of the body, although varying considerably in concentration in the different tissues. It is present in high concentration in the pituitary and adrenal glands, the corpus luteum and interstitial gonadial cells, and, to a lesser extent, in the liver. It is also present in the adreno-cortical homologues of certain fishes.

The suggestion is that vitamin C is essential for the existence of living protoplasm, probably as an integral part of an oxidation reduction system. Its high concentration within certain organs may indicate a non-specific catalysis of the manufacture of the hormones of those organs.

Plural Nature of Vitamin B

ONE group of rats was supplied with vitamin B carriers that had been subjected to intense ultra-violet irradiation. The animals developed a severe dermatitis and died. A second group received tikitiki, an alcoholic extract of rice polishings, as the sole source of vitamin B. After some ten or twelve weeks these rats became denuded, assumed a very miserable appearance, and finally they died also.

Wheat germ oil and flavines have unique properties in treating these abnormalities. The denuded condition is healed by either hepatoflavine or lactoflavine, and the rats grow rapidly on the combination of tikitiki and flavine. Wheat germ oil is ineffective. The dermatitis is not relieved by flavines, but is healed by wheat germ oil. Growth will not be sustained unless the irradiated supplement is fortified both by wheat germ oil and flavines. Ultra-violet irradiation destroys two vitamins. One is flavine, the other is the unidentified factor required to prevent dermatitis.

Rarity of the Archaic Arachnids, Podogona (Ricinulei)

THE writer of the review in NATURE of June 29 of Mr. Savory's book on Arachnida refers to a statement made by that author with regard to the number of specimens of Podogona or Ricinulei known to exist. The number of specimens representing the thirteen living species of Podogona was estimated at thirty-two.

This figure was correct when Kästner wrote his monograph on the group in Kükenthal and Krumbach's "Handbuch der Zoologie" (1932), but in the summer of the year 1933, Mr. Ivan T. Sanderson presented a collection of no less than three hundred and seventeen specimens of *Cryptostemma sjöstedti* to the British Museum (Natural History). These Podogona were collected by Mr. Sanderson on the Percy Sladen Trust Expedition to Nigeria and the British Cameroons, 1933. Only seventeen specimens were adult, the rest being nymphs except for one six-legged larval form. Mr. Sanderson also managed to bring back twenty living specimens, which were kept alive for twelve months in an incubator in the Museum. During this time they were exhibited at the Royal Society soirée in June 1934 and at the Linnean Society, and Mr. Sanderson had a very interesting film made showing their curious gait, and the cataleptic state induced by sudden intense light or slight movement.

The acquisition of this valuable collection and the light it has helped to throw on this obscure group tempt one to quote further from Mr. Savory's book and say it ". . . is a challenge to those collectors fortunate enough to find themselves in the right neighbourhood".

Surface Tension of Heavy Water

SELWOOD and Frost[1] obtained for mixtures of varying proportions of ordinary and heavy water different values of surface tension, the surface tension becoming smaller as the D_2O concentration increased. These authors compute by extrapolation that pure heavy water has a surface tension of 67·8 dyn./cm. at 20° C. No other data can be found in literature, especially no direct measurements of surface tension of pure heavy water.

When dealing with another problem, there arose a necessity of carrying out such a measurement with 99·2 per cent D_2O obtained from the Norsk Hydro-elektrisk Kvaelstofaktiebolaget, of Oslo, Norway.

Radius of the capillary bore (cm.)	Surface tension or ordinary water (dyne/cm.)	Surface tension of heavy water in dyne/cm.		
		I $d = 1·1053$	II $d = 1·1048$	III $d = 1·1049$
0·013526	73·0	72·7	72·6	72·6
0·019503	72·0	72·1	71·5	71·2
0·025364	72·4	—	71·8	72·0

Preliminary experiments carried out by means of the du Noüy precision tensiometer gave for this water a surface tension value of 72·6 ± 1 dyne/cm., the corresponding value for ordinary water being 72·8 dyne/cm. More accurate measurements were made by the ascension method at 20° C., all usual

precautions being taken. The results obtained in three capillary tubes of different radii show, for three samples (I, II and III) of more than 99 per cent heavy water obtained at different periods, a surface tension of 72·2 ± 0·5 dyne/cm. As may be seen from the accompanying table, this value does not differ from that known[2] for ordinary water, within the limits of our experimental error.

Measurements have been made also with 96 per cent and 94 per cent D_2O, the figures obtained being almost the same as those previously stated; densities and ascensions compensate each other similarly as in the case of 99 per cent heavy water.

On the basis of these preliminary measurements, we are inclined to believe that the values of surface tension of heavy and ordinary water most probably are equal or, in any case, the difference is very small.

Points from Foregoing Letters

H. FRÖHLICH and E. Guth claim that Temple's paradox (that if physical operators commute, Planck's constant is equal to zero), which would invalidate the greater part of the quantum theory, is due to the arbitrary way in which he chooses the product of three physical variables. Prof. Temple, while agreeing that in the case of triple products a unique form of representation cannot be derived, maintains that his deduction is as legitimate as that of Fröhlich and Guth. The paradox, he considers, really indicates that physical characteristics cannot be simultaneously described by classical variables and by quantum operators.

Prof. A. J. Dempster reports the observation by the mass-spectrograph of a uranium isotope of atomic weight 235, which is probably actino-uranium, the source of the actinium series of radioactive elements.

An X-ray polariser in which a cut section of a single crystal is used as scatterer is reported by Dr. W. H. George to give a beam of intensity 100–1000 times that of the standard methods.

Observations on infra-red light absorbed by ice, by water, and by heavy water dissolved in an organic liquid (dioxane) bring additional support, according to C. H. Cartwright, for a quasi-crystalline structure of water. The evidence favours a hindered translational frequency of D_2O or H_2O molecules, together with a turning of the four molecules surrounding the central vibrating molecule.

From a formula derived by Raman and Krishnan, relating optical and electro-magnetic properties of substances with molecular behaviour, Dr. R. J. W. Le Fèvre deduces that the polarisation of most substances in solution (as shown by the effect on the dielectric constant) should be less than in the vapour state; only those with a negative Kerr (magneto-optic) constant would show greater polarisation when dissolved than in the gaseous state.

Dr. I. W. Wark and Alwyn B. Cox describe instances of drops, apparently with contaminated surface, coalescing in several stages; they consider that the phenomena would repay study by means of a high-speed cinematograph.

Many British statisticians, Mr. H. J. Buchanan-Wollaston writes, assume that a test may be used simultaneously to show the untruth of one hypothesis and the truth of the reverse hypothesis. The reasoning employed, though often giving useful results, is open to objection and has apparently led to mistrust of these methods on the part of Continental statisticians.

The blue colour given by fish liver oils with antimony trichloride in chloroform solution has been used by Carr and Price as a rough indication of the amount of vitamin A, though it is also produced by other constituents of the oils. A. Emmerie shows how the colour reaction is affected by saponification of the oils and describes a method used to obtain in concentrated form the constituents responsible for the Carr and Price reaction.

Dr. H. Laser describes how the respiration of the retina tissue of rats, and of mouse-cancer tissue, differs in phosphate and in bicarbonate media. Small amounts of hydrocyanic acid inhibit the respiration of retina tissue in presence of phosphates, but do not affect it in bicarbonate solution.

Chemical investigation of glycogen obtained from fish liver indicates that its molecule contains 12 glucose units and, according to Dr. David J. Bell, is identical with the glycogen obtained from the liver of rabbits.

Dr. V. Korenchevsky finds that, by the injection of a derivative of male sex hormone (androsterone) into female rats from which the ovaries have been removed, certain vestigial organs (periurethral glands) are stimulated to develop into a structure typical of the ventral lobe of the prostate of the male. He suggests that the two organs are homologous in the male and female.

Depigmentation in young rats described by Dr. F. J. Gorter is prevented or cured by addition of copper to the diet. He finds that the dosages required vary considerably in consequence of the availability of the copper fed to the rats and of certain dietary factors, which are always present to some degree in well-balanced rations and counteract the copper.

Vitamin C (ascorbic acid) appears to be a constituent of every living cell, according to experiments by Dr. Geoffrey Bourne and Russell Allen. Using acetic acid – silver nitrate reagent, which gives a black stain with vitamin C, they find small black granules scattered in the protoplasm in the cells of even the lowest organisms.

Further light on the plural nature of vitamin B is thrown by experiments, briefly reported by Prof. Albert G. Hogan and Luther R. Richardson, showing that alcoholic extract of rice, wheat germ oil and flavines, differ in their ability to cure dietary deficiency diseases in rats.

Dr. Susan Finnegan recalls the unique collection of 317 specimens of the rare African arachnid *Cryptostemma sjöstedti* presented to the British Museum by Mr. I. T. Sanderson and directs the attention of suitably placed collectors to the need of further specimens representing the thirteen living species of the order Podogona.

Research Items

Eskimo Migrations

THE bearing of recent researches on the vexed problem of Eskimo migration and cultures is discussed by Dr. T. Mathiassen in an article in the *Geographical Review* of July. He regards the Thule culture as originating in Asia and representative of the first Eskimo migration from west to east across Arctic America and into Greenland by Smith Sound. The Bering Sea culture of St. Lawrence Island he believes to be older than the Thule culture, and puts the Eskimo settlement of Alaska much further back than was previously assumed. Dr. Mathiassen disagrees with Mr. Birket-Smith's theory of the first peopling of Alaska from the east by Palæo-Eskimo who were derived from the primordial Eskimo on the Barren Grounds of Canada. The Caribou Eskimo are not the last survivors of these primordial Eskimo whose descendants adopted a sea culture, but rather a residual offshoot of a coastal people. The Cape Dorset culture of Labrador and the eastern shores of Hudson Bay, described by D. Jenness, would seem to be derived from the Thule culture and not from the Caribou Eskimo, but the question arises whether the people who left this culture in Labrador were not Indians rather than Eskimo.

Mixtec Indian Manuscript

MISS EMMA REH, the Washington archæologist, whose recent investigations of Mexican antiquities have aroused considerable interest, has brought to light a Mixtec manuscript, which holds out the prospect of an interpretation of the Mixtec system of picture-writing. The manuscript is now in the National Museum, Mexico City. It came originally from the State of Oaxaca in southern Mexico. According to a report issued by Science Service, Washington, D.C., it is of deerskin and is in the form of eleven folds or pleats, reading from back to front. The contents are in black and consist of pictures, glyphs and writing in the European script, the last-named feature, obviously, giving the manuscript its special value, as it is hoped that it may thereby be possible to effect a translation of the writing in pictures and glyphs. The picture-writing suggests that the manuscript is a family chronicle of a chiefly house. It opens with a picture of three figures, who evidently, to judge by their dress, are of high rank. Their names are indicated as "Two Alligator", "Four Deer" and "Nine Dog". The story begins in the Indian year "Three House" and on the second page the date 1300 appears in European figures. Up to the eighth page the names are given in hieroglyph, but on the ninth page, Spanish names, and even Spanish clothes, appear as well as the Christian cross. This change is dated 1610, and may coincide with the adoption of the Spanish honorific 'Don' and 'Doña', a privilege granted to the Indians by the Spanish crown. The record ends in 1684. It has been suggested that it may be something in the nature of a "proof of nobility", or a document similar in purpose to the 'maps' or agreements defining boundaries, some of which are known still to be in use in Oaxaca. They are never seen by any but the Indian elders.

Marquesan Shell Coronet

A PECULIAR type of head-dress from the Marquesas Islands has been presented to the British Museum by the Christy Trustees (*Brit. Mus. Quart.*, 9, 4). It resembles a coronet, and is composed of thin plaques of conch-shell and turtle-shell arranged alternately. These are attached by threads of coconut fibre to a 'woven' band of the same material. The shell plaques are left plain, but those of turtle-shell are ornamented with figures carved in low relief in the conventional style typical of Marquesan art. The main design consists in each case of a central full-faced figure, flanked by two smaller inward-facing figures in profile. Originally there should probably have been three rows of pearl-shell discs with turtle-shell rosettes attached as an additional ornament to the surface of the sennet band. These head-dresses (*paekaha*) were formerly worn on festive occasions by both sexes. Their manufacture probably originated in Fatu Hiva in the southern islands of the group. The coronets were worn in historic times with the sennet band uppermost, so that the shell plaques formed a kind of eye-shade. The carved figures were thus worn the wrong way up, which suggests that the original method of wearing was the reverse. Good early examples are difficult to obtain, and this is the first complete specimen to appear in the Museum collections. The modern degenerate version of the coronet has celluloid or vulcanised rubber in substitution for the turtle-shell, and porcelain buttons for the pearl-shell discs.

Daylight and the Feeding of Birds

THE relationship between the coming and departing of daylight and the feeding of some common birds has been discussed by George Marples (*British Birds*, 29, p. 45, July 1935). He shows that the habit is a tolerably regular one, and that amongst the birds which begin to feed before sunrise (the time anteceding sunrise by from 42 minutes to 5 minutes) are the song-thrush, mistle-thrush, redbreast, barn-owl, backbird, wren, blue tit, great-tit, chaffinch, house-sparrow; while such as begin to feed after sunrise include only the goldfinch, coal-tit and spotted flycatcher. A regular cessation of feeding in relation to sunset was also observed. A peculiarity brought out by comparison of the times recorded is, that almost invariably blue-tits commence to feed before great-tits and finish feeding later, notwithstanding that they eat the same sort of food and the great-tit has a larger body to nourish.

Crustacea of Porto Rico and the Virgin Islands

Two important papers have recently been published by the New York Academy of Sciences on the "Scientific Survey of Porto Rico and the Virgin Islands"; these deal with the Crustacea Macrura and Anomura by Waldo L. Schmitt, and the amphipods by Clarence R. Shoemaker (New York, Jan. 1935). An endeavour is made in both papers to include every species known from these two regions including St. Croix, and a brief description of generic or specific characters is given in most cases. When many species represent a genus,

useful keys are employed and at least one species of each genus is figured. 142 species, 68 genera and 24 families of macruran and anomuran Crustacea are listed, a very large number of these having been collected by the expedition, which only undertook shore and shallow-water marine and fresh-water collecting. The amphipods are not so well known; fourteen families, twenty-one genera and twenty-four species are recorded. A revision of the genus *Emerita* with a new species (the only one found in Porto Rico) has resulted in Dr. Schmitt recognising seven species, four of which are found on the Atlantic coast of America, and two on the Pacific coast, whilst he finds that the Indo-Pacific form known as *Emerita asiatica* was first named by Linnæus as *Cancer emerita*, and should now be called *Emerita emerita*.

North American Callianassas

DR. WALDO L. SCHMIDT, in his paper "Mud Shrimps of the Atlantic Coast of North America" (Smithsonian Miscellaneous Collections, 93, No. 2, 1935), describes three new species of *Callianassa* and a new variety of one of them, proposes a new name for a specimen that had been assigned to an old, inadequately described species, and gives a general survey of all species occurring on the Atlantic coast of North America, with a useful key. One of the new species, *Callianassa* (*Callichirus*) *islagrande*, somewhat resembles *C. major*, Say, but differs in the eye stalks, telson and the remarkably elongate larger chela of the male. The genus *Glypturus*, as de Man has already suggested, is shown to be so similar to *Callianassa* that the present author now no longer separates it, placing *Glypturus acanthochirus*, Stimpson, in the sub-genus *Callichirus*, which shows a number of species having the third maxillipeds approaching the *Glypturus* type, the generic characters being based on these appendages. The paper is illustrated with photographic plates showing the dorsal front view of the various species and some of the more important limbs.

Marine Worms from Hawaii

IN Bulletin 129, Bernice P. Bishop Museum, Honolulu, 1935, M. Holly describes a collection of polychætes most of which are pelagic forms of *Nereis* captured on the surface of the sea, especially by night. All the nereids except one known species are represented by epitokous forms, all of relatively small size—3–20 mm. long—which are placed in ten new species. A detailed account of their characters is given. In *Occasional Papers*, 10, No. 18; 1934, from the same Museum is a brief note by Prof. W. R. Coe on new nemerteans from Hawaii, in which he points out that the tropical and subtropical coasts bordering the Pacific Ocean have a sparse representation of nemertines as compared with the coasts of more northern latitudes. The specimens here described, collected in the intertidal zone, include three species of the genus *Baseodiscus*, one of which is described as new. In two of the species some of the efferent ducts of the nephridia lead to the cavity of the foregut and others open on the dorso-lateral surfaces of the body.

Aquatic Hemiptera of the Family Helotrephidæ

THE family Helotrephidæ is one of obscure affinities and shows the very exceptional character, among adult insects, of the head and thorax being closely fused together. Mr. W. E. China has published an important paper wherein some new or little-known species are described and figured (*Ann. Mag. Nat. Hist.*, June, pp. 593–614). At the same time the taxonomy of the family is reviewed, and stress is laid upon those characters which are of special generic and specific value. These features are listed, and will serve as a guide to future workers, and so avoid the use of lengthy, detailed descriptions which may include the enumeration of characters devoid of real diagnostic value. The paper concludes with a key to the known genera and species. This small and peculiar family, it may be added, is only known from the Orient and Central Africa.

A Disease of Coniferous Trees

EXOTIC conifers have been imported into New Zealand for half a century. They have been acclimatised, and have usually formed healthy forests of valuable timber trees. It is scarcely a matter of wonder that one or two fungus diseases have also been imported inadvertently, but these have largely been controlled by avoiding unsuitable sites and high altitudes. A rather more severe disease made its appearance in 1929, and has been studied in detail by Mr. T. T. C. Birch ("A Phomopsis Disease of Conifers in New Zealand". N.Z. State Forest Service Bulletin No. 7. Govt. Printer, Wellington, N.Z. 1*s.* 9*d.* net. Pp. 30. 1935). The causal fungus, *Phomopsis strobi*, produces a canker upon the stems and makes the terminal shoots wilt. Young trees of *Pinus radiata*, *P. muricata* and *P. canariensis* are the hosts, but infection only occurs in late winter when unseasonable frosts overlap the growing season of the susceptible species. Cultural and morphological characters of the fungus have been investigated, and conditions of infection have been demonstrated by extensive experiment. Eighteen half-tone illustrations elucidate the structure of the fungus and portray the symptoms it produces.

Pests and Diseases of Sugar-Beet

THE Ministry of Agriculture and Fisheries has added another volume to its series of monograph bulletins on plant diseases ("Pests and Diseases of the Sugar Beet", Bulletin No. 93, pp. 58, April 1935, 1*s.* 6*d.* net. H.M. Stationery Office). The insect and other pests have been described by Mr. F. R. Petherbridge, whilst the fungus and virus diseases are treated by Mr. H. H. Stirrup. These two workers made an extensive tour of the chief sugar-beet growing areas in most of the countries of central and northern Europe, and the bulletin describes the information they collected. Most of the Continental pests are also troublesome in Great Britain, but the beet leaf bug (*Piesma quadrata*), the meadow moth or webworm (*Loxostega sticticalis*), sugar-beet weevils (*Bothynoderes* sp. and *Otiorrhynchus ligustici*) and the beet eelworm (*Heterodera schachtii*) have not yet appeared here. The virus diseases known as 'yellows' and 'crinkle' also seem to be mainly of Continental occurrence. An exhaustive list of English diseases and pests is given, each malady being described in detail. One of the most pleasing features of the volume is the publicity given to various Continental methods of control. English readers will be interested in a machine furnished with four rotary brushes which gently remove the eggs of the beet fly (*Pegomyia betae*) from their intended victims. Twenty-six half-tone illustrations help to render the bulletin an attractive and clear exposition of the subject.

The Photographic Objective

AN interesting account of the development of the photographic lens was given recently as an address to the Physical Society by W. Taylor and H. W. Lee (*Proc. Phys. Soc.*, May). The ordinary photographic lens has employed exclusively spherical surfaces, and successive improvements have removed one after another of the aberrations. The article describes the achromatic doublet, Lister's combination of doublets to correct coma, the Wollaston meniscus construction to correct astigmatism, and the combination of meniscus lenses to correct distortion. It next became necessary to increase the aperture of the lens, and the Petzval portrait lens appeared, followed by the 'rapid rectilinear' and the anastigmats using the new Jena glasses. H. D. Taylor in 1893 broke away from the traditional line of development and introduced an anastigmat with only three lens elements. Modern lenses are descended either from the Jena anastigmats, the Petzval lens or the H. D. Taylor lens. Diagrams of a number of modern lenses are given, including the Zeiss $f/0{\cdot}85$ lens (derived from the Petzval), various British lenses working up to $f/1$, and special variable focus and telephoto lenses. There is a list of references to patents.

Molecular Polarisation in Solution

IT is now known that the dipole moment of a substance measured in solution is influenced by the nature of the solvent, and some empirical rules have been proposed with the object of correcting for the solvent effect. By the examination of a number of experimental results, R. J. W. Le Fèvre (*J. Chem. Soc.*, 773; 1935) concludes that the expression ${}_0P_1/{}_0P_2 = K(\varepsilon_2 + 2)/(\varepsilon_1 + 2)$, where ${}_0P_1$ and ${}_0P_2$ are the orientation polarisations of a solute molecule in two media of dielectric constants ε_1 and ε_2 respectively, appears to be valid over a wide range of ε values. It satisfactorily includes the polar solvents chloroform, aniline and chlorobenzene, whilst a rule previously given by Jenkins that the total polarisation is inversely proportional to ε fails in this respect. A rule proposed by Müller, that ${}_0P_{\text{soln.}}/{}_0P_{\text{gas}} = 1 - k(\varepsilon - 1)^2$, is found to hold only for solvents of low dielectric constant, for which $k = 0{\cdot}075$; it fails for chloroform ($k = 0{\cdot}032$) and chlorobenzene ($k = 0{\cdot}035$). The recorded data show that a non-polar solute has much the same molecular polarisation in all solvents: only polar solutes exhibit appreciable alterations. Since the sum of the atomic and electronic polarisations of a substance is usually practically independent of its state of aggregation, these differences are wholly referable to the orientation polarisation, the variations of which are now shown to be simply related to the dielectric constant of the medium (see also p. 181 of this issue).

Action of Calcium Carbide on Methyl Alcohol

STATEMENTS occur in chemical literature to the effect that, when free from water, alcohols do not react with calcium carbide. So far as methyl alcohol is concerned, this seems to be erroneous. The results of experiments by Prof. A. Contardi and Dr. B. Ciocca (*Rend. R. Ist. Lombardo Sci. e Lett.*, **68**, parts 1–5) show that absolute methyl alcohol acts readily on powdered calcium carbide. The reaction begins even at the ordinary temperature and gives rise to calcium methoxide and acetylene, no homologues of which are formed. It is, therefore, evident that the determination of water in mixtures of hydrocarbons and alcohols by measuring the acetylene formed by their interaction with calcium carbide will not give trustworthy results unless methyl alcohol is absent. The reaction described furnishes a simple means of obtaining calcium methoxide, the preparation of which is otherwise a laborious operation.

Carob Flour as a Foodstuff

IN parts 1–5 of vol. 68 (1935) of the *Rendiconti of the Reale Istituto Lombardo di Scienze e Lettere*, Prof. Adriano Valenti, of the University of Milan, gives the results of experiments in which rats and dogs were fed with carob germ flour, either raw or roasted, and in some cases boiled with water. The flour, prepared by grinding finely the germs of the carob seeds, has a sweetish taste and adheres to the palate like a gummy material. Its percentage composition was found to be: water, 8·95; proteins, 55·30; fats, 5·21; lecithin, 1·34; ash, 6·70; cellulose, 2·32; carbohydrates, 20·18. It thus appears to be richer in protein than any other food of vegetable origin. The biological experiments show, nevertheless, that it is tolerated perfectly as a food by animals. With none of the rats (26) was any ill-effect observed, and regular increase in weight occurred, particularly with young, growing animals. The rats compared well with those of a second group fed on a diet of bread and milk. Similar results were obtained with two dogs, one of which was fed, first on bread and water, then on the carob flour, and later on bread and water again; with the other dog, part of the bread in the initial and final stages was replaced by horseflesh.

Lunar Heights and Topography

MESSRS. MCMATH, Petrie and Sawyer have developed a new technique for investigating lunar topography at the McMath-Hulbert Observatory of the University of Michigan (*Publications Obs. Mich.*, 6, No. 8). They find that an isolated determination of the height of a lunar peak, derived from a measured shadow length, is of little significance, on account of the rugged nature of the country over which the shadow is passing. The Michigan workers investigate the variation of these relative altitudes with changing shadow lengths, and so determine the topography of the neighbouring peaks and crater walls and secure the average elevation of such points above the surrounding country. Motion picture negatives are used; these are exposed in a modified motion picture camera attached to the 10½ in. Cassegrain reflector. A typical set of exposure times runs from 24·0 sec. to 17·9 sec. with an interval of 4·0 sec. between exposures. After development, the negative is run through a projector which magnifies the picture to a scale of 1·15 mm. per second of arc on the moon. A profile of a section through the crater Theophilus is given by the authors. The outer ramparts are 15,000 ft. and 14,000 ft. and the central peak 7,500 ft. above the adopted datum level, below which the floor of the crater sinks 1,000 ft. in places. This section through the crater is 65 miles from rampart to rampart. The uncertainty is given as being ± 125 ft. for the elevation of a peak 16,000 ft. above the average of the terrain in its vicinity.

ERRATUM: Referring to the paragraph entitled "Sex and Cultural Status" in NATURE of July 27, p. 149, Dr. J. D. Unwin informs us that the word "zooistic" should read "zoistic" throughout.

The Origin of Optical Rotatory Power

By Prof. T. M. Lowry, C.B.E., F.R.S.

PROF. MAX BORN'S paper on the "Theory of Optical Rotatory Power", which was read at the Royal Society on February 7 and is published in the *Proceedings* for May 1, 1935, is of first class interest and importance, since it provides an adequate solution of one of the most difficult problems in optics.

More than a century ago, Fresnel suggested that optical rotatory power was caused by the unequal velocities of transmission of circularly polarised light of opposite signs; and by a brilliant piece of experimental work he established the real existence of *circular double refraction* in quartz; but his tentative suggestion that the optical rotation of rock crystal "cannot be reconciled with complete parallelism of the molecular lines", and must therefore depend on a spiral arrangement of these layers, cannot be extended to optically active liquids. It was therefore left to Pasteur to recognise in the phenomenon of *dissymmetry* (that is, the inability of a figure to be superposed on its image in a mirror) the characteristic feature of right-handedness and left-handedness, which determines the existence of optical rotatory power in crystals and in liquids, and finds its simplest expression either in a spiral or screw-like structure or alternatively in an irregular tetrahedron.

Equations expressing the influence of wave-length on rotatory dispersion were developed in 1900 by Drude; but these were based primarily on an intuitive recognition of the correct mathematical form of the equations; and, although Drude pointed out that "a dissymmetrically isotropic medium would result if all the molecules were irregular tetrahedra of the same kind", he made no attempt to prove that his conception of *ions vibrating in helical paths* would actually give rise to optical rotation. So recently as 1916, therefore, Gray was justified in complaining that the chemical and physical theories of optical rotatory power "have not been tied together; it has not been shown why the asymmetric molecule should give rise to these particular equations".

The missing link was supplied in 1915 by Born's theory of *coupled vibrators*. The form of *coupling* suggested by Born is of the simplest and most inevitable character, and has been adopted almost universally by subsequent workers in the same field. It is merely an application of the phenomenon of electrical resonance, and implies that, when an electrically charged particle is set in vibration, for example, by an incident light-wave, it sends out a secondary wave, which acts upon neighbouring particles in just the same way as the original light-wave. The difficulty of the problem of optical rotatory power arises from the fact that rotation of the plane of polarised light is a *third-order effect* which does not appear until *four* particles have taken part in this process of resonance. No rotation is therefore produced until the original vibration has been handed on from A to B, C and D; and even then the effect is a precarious one, which vanishes if the four particles lie in the same plane, or if in any other manner a plane or centre of symmetry is created, for example, by making two of the particles identical. In these circumstances the calculation of optical rotatory power proved to be such a formidable task that it was only attempted twice in a period of twenty years; and even then one of these laborious calculations of the rotatory power of a *crystal* was vitiated by a numerical error, which has not yet been put right.

The four coupled vibrators of Born's theory obviously correspond closely with the four dissimilar radicals which give rise to optical rotatory power in the simplest optically active molecules, namely, those molecules which contain an asymmetric carbon atom of the type $C\,R\,R'\,R''\,R'''$; but the calculations of the rotatory power of an asymmetric *molecule* on the basis of Born's theory are so difficult that they have never even been attempted. Two attempts have been made, however, to simplify this extremely complex problem. Thus S. F. Boys, by ignoring the characteristic frequencies of the vibrators, was able to calculate the rotatory powers of four simple alcohols and amines, from the radii and the refractivities of the radicals; and values of these quantities were found which, when inserted in an extremely complex function of the linear dimensions of the molecule, and multiplied by a simple product of the refractivities and other appropriate constants, gave a remarkable concordance between the observed and calculated specific rotations. On the other hand, Werner Kuhn, in 1929, applied Born's theory of coupling to a simplified molecular model consisting of two *linear vibrators*, moving at right angles to one another (Fig. 1). Optical rotatory power then occurs as a *first order effect* and can therefore be expressed by much simpler formulæ. He showed that his model gave the formulæ for rotatory dispersion which had already been developed by Drude and Natanson, and that these formulæ then had a self-consistent basis, whereas the spiral vibrators, which Drude suggested as a justification of his formulæ, do not actually give rise to any rotatory power at all.

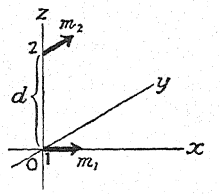

FIG. 1.* Kuhn's simplified model of a dissymmetric molecule.

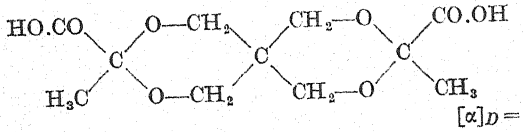
The postulate of a linear vibrator implies that the ellipsoid of elasticity is reduced to a straight line, so that the particle is able to move to and fro in one given direction, but is so rigidly confined to this linear path that no polarising force, however powerful, is able to make it move in any other direction. Such a conception differs very widely from the relatively flexible electronic systems which are found in chemical

* Figs. 1, 2 and 3 are reproduced by courtesy of Messrs. Longmans, Green and Co., Ltd., from Lowry's "Optical Rotatory Power" (1935).

molecules. It is perhaps approached rather remotely in substances like benzoquinone, the crystals of which contain giant molecules of indefinite extension in one dimension, along which they exhibit abnormally high refractivities; but substances like amyl alcohol give no hint of any similar strong anisotropy. Moreover, the presence of *four* dissimilar radicals appears to call inexorably for a system of *four* vibrators; and calculations based upon a model containing only *two* vibrators can only have a remote relation to the properties of real molecules of this type. Whilst, therefore, Kuhn's simplified model has provided a new basis for the dispersion formulæ of Drude and Natanson, it does not appear to be capable of direct application to the asymmetric carbon atom, the rotatory power of which must still be treated as a third-order effect in accordance with the original conceptions of Born.

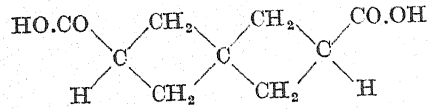
More favourable conditions occur in certain spiro-compounds, which are not asymmetric (since they possess a two-fold axis of symmetry) and do not contain an asymmetric carbon atom, but which can nevertheless be prepared in optically active forms, since they possess the essential property of molecular dissymmetry, that is, the molecule can exist in two mirror image forms which are not superposable on one another. Three such molecules have been studied in this connexion.

I. *Erythritoldipyruvic acid*, resolved by Boeseken and Felix (*Ber.*, 56, 1855; 1928).



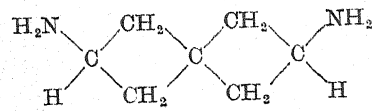
$[\alpha]_D = \pm 4°$.

II. *Spiroheptanedicarboxylic acid*, resolved by Backer and Schurink (*Proc. Akad. Wiss., Amsterdam*, 31, 370; 1928).



$[M]_D = +2°$.

III. *Diaminospiroheptane* resolved by Pope and Jansen.



$[M]_{5461} = +18°$.

In each of these compounds the two halves of the molecules are crossed, that is, if the right-hand ring is in the plane of the paper, the left-hand ring is in a plane at right angles to it, since the central carbon atom has a tetrahedral and not a planar configuration. The planes which contain the terminal radicals COOH and CH_3, COOH and H, or NH_2 and H, are therefore also at right angles to one another. These two rectangular planes can be compared with the directions of the two linear vibrators in Kuhn's original model, and on this basis he has made a detailed study of Boeseken's spiro-acid I. For this purpose he has considered the two —CO.OH groups as linear vibrators, displaced from the central axis of the molecule in directions at right angles to one another (Fig. 2), and has thus been able to calculate the rotatory power of the molecule.

This figure has the demerit of dealing with only one of the two radicals in the system CH_3—C—CO.OH, the 'crossing' of which produces the dissymmetry of the molecule. Born, on the other hand, has deduced a formula for the rotatory power of a system of four vibrators, *A*, *B*, *A*, *B* (Fig. 3), in which *both* radicals play a part and neither of them need be assumed to be strongly anisotropic. This formula has been applied to the spiro base of Pope and Jansen, where there are good reasons for thinking that spacial dissymmetry, and not the anisotropy of the H and

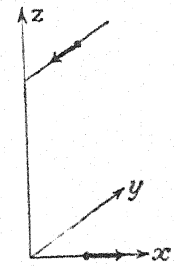


FIG. 2. Coupled vibrators in a dextrorotatory molecule.

NH_2 radicals, is the principal factor in producing the optical rotatory power of the molecule. Results of the right order of magnitude have been obtained; but these are merely guesses, and the principal importance of the formula lies in its application to the *relative* magnitudes of the rotatory power of related compounds, rather than in attempts to predict the *absolute* rotatory power of any of them. The latter must always be difficult, since the formula involves the *eighth power* of the distance between the two vibrators, the *sixth power* of their frequencies and the *square* of the strengths of their absorption bands. On the other hand, if we compare a series of spiro-compounds containing, for example, the radicals

—NH.CO.NH_2 —NH.CO.CH_3 and —NH.CO.C_6H_5

we can now recognise that their rotatory powers are definite functions of three well-defined properties of

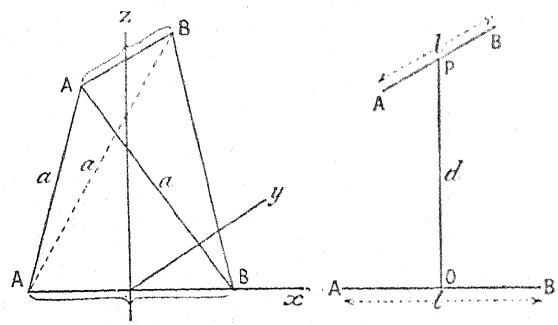

FIG. 3. Born's molecular model.

the radical, and their correlation becomes an experimental problem of very great interest. Unfortunately, the frequencies of the simplest compounds lie in the Schumann region, for which very few data are yet available; but no great increase of complexity is needed in order to bring the frequencies within the range of easier experimental observation; and, on the other hand, the Schumann region is rapidly being opened up to research, so that progress on the lines suggested by Born's theoretical work need not be long delayed.

A Note on Stereoscopic Photography

By Dr. John R. Baker, Department of Zoology and Comparative Anatomy, Oxford

IT is sometimes stated that in the stereoscopic photography of near objects it makes no difference at all to the images whether the cameras are placed parallel to one another, or convergent upon the object.

In Fig. 1 the object to be photographed has three distinct points upon it, A, B and C. The thick black

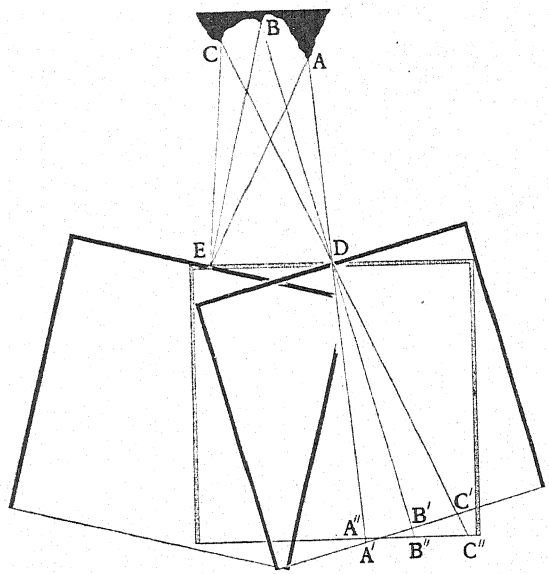

FIG. 1.

lines indicate the outlines of the camera in its two positions for obtaining convergent views of the object. (The angle of convergence shown in Fig. 1 is purposely made greater than the greatest angle of convergence possible with normal vision, so as to exaggerate the point that is to be made.) An exactly similar camera is also shown in the position it would occupy for the right-eye view, if photographs were going to be taken with parallel cameras. The outline of this camera is indicated by dots between lines. For the sake of simplicity pin-hole cameras are represented. The apertures of both pairs of cameras are at D for the right-eye view and at E for the left-eye view.

The right-eye convergent camera produces images of the points A, B and C at A', B' and C'. The right-eye parallel camera produces the images at A'', B'' and C''. Now $A'B'$ exactly equals $B'C'$, while $A''B''$ is less than $B''C''$. Therefore the view obtained with the convergent camera is not the same as that obtained with the parallel camera.

Which is the proper position of the camera for the representation of normal binocular vision as closely as possible? Imagine an eye situated at D. The owner of the eye would notice that the angle subtended between A and B was exactly equal to the angle subtended between B and C. In making an accurate drawing of the appearance of the object from his viewpoint, he would therefore make AB exactly equal to BC on his sheet of paper. This is what the convergent camera does. The convergent camera therefore gives the proper representation of the object.

The parallel camera has the advantage of giving a larger field of view in focus at the same time, if lenses of wide aperture are used and if the object presents a more or less flat surface at right angles to the axis of the cameras; but its image is not absolutely accurate. It must be remembered that in stereoscopic photography one is relying for one's effects upon minute differences between the two prints, and extreme accuracy is therefore important if a truthful appearance is to be given.

The facts stated in this note give support to the tilting-stage method of stereo-photomicrography, for in this method the two views are convergent. The other method, in which the object is photographed first at one side of the field of view and then at the other, and the two photographs treated as a stereoscopic pair, is equivalent to the use of parallel cameras.

International Co-operation in Astronomy

THE International Astronomical Union held its fifth general assembly at Paris on July 10–17, at the Centre Marcelin Berthelot, when nearly three hundred astronomers were gathered together from twenty-seven different countries. The President of the French Republic was present at the opening ceremony, when addresses of welcome were given by the Minister of Public Instruction, the president of the French National Committee of Astronomy (M. de la Baume Pluvinel), the director of the Paris Observatory (M. Esclangon) and replied to by the president of the Union, Prof. F. Schlesinger. During the meeting the adhesion of three new countries, U.S.S.R., China and Yugoslavia, was announced; with the growing number of countries supporting the Union it was found possible substantially to reduce the unit of subscription from the different countries, without hindering the work which the Union has already undertaken to support.

A great part of the value of the meeting lies in the informal discussions between small groups which were possible at some of the social gatherings organised by the generously hospitable French hosts, such as the visits to the observatories at Meudon and Paris. But the work of the Union is done mainly at the meetings of thirty-one committees which

examine schemes of co-operative work in the different branches of astronomy. One of the features of the present meeting was the number of joint meetings of commissions, which after dealing with their own special work, discussed jointly borderline problems where their common interests were concerned. Thus the commissions on ephemerides, meridian astronomy, and the movements and positions of planets, asteroids and satellites combined to discuss and press for further experimental work—to be followed later by international co-operation schemes for the determination of systematic corrections to star positions from observations of minor planets. To the commissions on notations and ephemerides were referred two resolutions on the symbols at present in use for time, which had been sent in by two national committees on astronomy. They recommended, and the Union adopted their point of view, that the symbol G.C.T. for Greenwich mean time reckoned from midnight should be dropped and that the symbol U.T. (Universal Time) should be used instead.

A move of the Bureau of Latitude Variation from Mizusawa to Naples on the coming retirement of Dr. Kimura was decided upon. Special tributes were paid to Kimura's work and he was made a *Président d'Honneur* of the commission on latitude, a similar compliment being paid to Sir Frank Dyson by the commission on meridian astronomy. The commission on spectrophotometry directed attention to the fundamental importance of producing photographic plates of uniform sensitivity over the surface, and urged further work on this point at the research laboratories of the various plate manufacturers. The physical study of comets was removed from the commission on planets and satellites, and in a general rearrangement of subjects the zodiacal light, the night sky and related subjects were grouped with meteoric astronomy, while novæ were given a special sub-commission in the commission on stellar spectra. The commission on lunar nomenclature, which has completed its work and published a map of the moon with a list of lunar formations, has been replaced by a new commission on the moon to deal also with occultations and physical researches.

Among the resolutions adopted on the recommendations of the committee on stellar statistics we may mention a definite choice of the galactic pole at $\alpha = 12^h40^m$, $\delta = +28°$ (1900·0), the position used in Ohlsson's tables of galactic co-ordinates. In solar physics resolutions were adopted for co-operative work on line profiles, for the publication of characteristic solar numbers of the sun separately for the four quadrants, N.E., N.W., S.E. and S.W., and for observations of active prominences at short intervals by a number of different methods. A number of technical resolutions on star positions cannot very well be given here but mention may be made of a resolution to issue a supplementary list of observatories and astronomers, of alterations in the cipher code for astronomical telegrams and of a preliminary list of notations prepared by Prof. Strömgren, the president of the commission on notations, and left until the next general assembly for further discussion and examination by those interested.

The volume of draft reports prepared by the presidents of commissions, well above two hundred pages in length, contains much valuable work but can be left over for review when the complete volume is printed.

One feature of great value at the meeting was an exhibition of astronomical apparatus, photographs, spectra, etc., arranged by the French National Committee with the co-operation of observatories and optical firms. This was open throughout the meeting and proved most successful. It was organised by the Comte A. de la Baume Pluvinel and M. Jules Baillaud. The latter acted jointly with M. A. Lambert as secretaries of the local committee, and to their unstinted efforts the success of the meeting was mostly due.

At the final meeting of the general assembly the following were elected as the executive committee to hold office until the next general assembly, to be held at Stockholm in 1938: *President*: M. Esclangon (France); *Vice-Presidents*: Dr. Adams (U.S.A.), Prof. Banachiewicz (Poland), Prof. Bergstrand (Sweden), Prof. Bianchi (Italy) and Dr. Spencer Jones (Great Britain); *General Secretary*: Dr. Oort (Netherlands).

Zooplankton of the Great Barrier Reef

A NOTABLE addition to the reports of the Great Barrier Reef Expedition has recently appeared*. In the first part the validity of the collecting methods is discussed, the effect of the transparency of the water and the relative abundance and composition of the zooplankton, with a comparison of temporary and holoplanktonic animals. Oblique hauls were made to ensure large enough catches to give significant results, and vertical hauls through a water column of known depth were made to give information directly comparable with data obtained elsewhere. The methods used are shown to be reliable.

Curves of the average catches of all animals for each month in the coarse silk net oblique and vertical hauls at a position three miles east of Low Isles in the Barrier Reef Lagoon agree well on the whole. Taking the copepods alone, the agreement is even closer, the month of January being the only one where there is any considerable disagreement, when many more copepods occurred in the vertical hauls. Daylight samples compare with those taken by night in a very similar way to those taken at Plymouth. The transparency of the water, which has already been shown to have a direct connexion with the wind (Orr, Vol. 2, No. 3 of these Reports), has a considerable effect on the numbers of animals caught, the curves of abundance in both oblique and vertical hauls, of copepods, decapod larvæ and chætognaths following closely the curve of transparency. There seems to be practically no seasonal variation in

* British Museum (Natural History). Great Barrier Reef Expedition, 1928–29. Scientific Reports, Vol. 2, No. 6: The Zooplankton. (2): The Composition of the Zooplankton of the Barrier Reef Lagoon, by F. S. Russell and J. S. Colman; (3): A Comparison of the Abundance of Zooplankton in the Barrier Reef Lagoon with that of some Regions in Northern European Waters, by F. S. Russell. Pp. 159–201. (London: British Museum (Natural History), 1934.) 7*s*. 6*d*.

numbers of copepods and decapod larvæ although there is one in the chætognaths.

Copepods, as is the case throughout the world, are the most abundant animals in the plankton. Here they form 71 per cent of the zooplankton in the vertical hauls, and this is supported in the oblique hauls, where they form 69·1 per cent. Other animals of importance were tunicates (Appendicularians and Thaliacea), chætognaths, molluscs (Pteropoda, Heteropoda and larvæ), echinoderm larvæ (November and December), ostracods (March and July), decapod larvæ and Siphonophora. Sudden increases and certain seasonal changes in echinoderm larvæ, ostracods and salps will be discussed in a later report.

It is estimated that the temporary planktonic animals, consisting of medusæ, coral planulæ, the larvæ of polychætes, cirripedes, decapods, euphausiids, stomatopods, gastropods, lamellibranchs and echinoderms, and larval fish, form about 10–15 per cent of the whole plankton taken in the coarse silk net vertical hauls and coarse mesh oblique and stramin oblique hauls. Gastropod, lamellibranch and echinoderm larvæ (the last restricted to a very short period), decapod and euphausiid larvæ are the most important. Of the last two, the decapod larvæ were usually more abundant, although euphausiid larvæ occurred in large numbers at times. In the stramin net catches the decapod larvæ were easily the most abundant representatives of the temporary plankton, an interesting form occurring frequently being *Leptochela pugnax*. The rarity of coral planulæ is striking, and compared with northern waters there were few cirripede nauplii.

A comparison of these results from the Great Barrier Reef lagoon with those of the International Council for the Exploration of the Sea in northern European waters in 1910 and 1911, where a Nansen net of silk No. 3 was of exactly the same dimensions as the coarse silk net used for the above experiments, is of great interest. Also more recent catches off Plymouth are compared. It was found that the Barrier Reef zooplankton is as rich numerically when averaged over the year as that of the northern regions compared. The great seasonal changes in the latter show much larger increases and decreases in the individual months. Comparisons in volume show that the Barrier Reef samples have more volume but fewer animals, to be accounted for by the greater compactness of the northern plankton.

Temperature must be taken into account in these comparisons, and the much higher rate of metabolism probable in warmer waters; also that there is apparently no surplus plant life at any time as there is in colder seas after diatom outbursts. The hydrographical and weather conditions are such that the diatoms are continually in a state of suspension and do not sink. It seems probable that throughout the year the animal plankton population is the maximum that the plant crop can support and that there is a comparatively rich supply of plankton animals available as food. Is there enough for the huge number of animal eating corals? It would seem that there are fewer plankton-eating fishes than in northern waters, where clupeoids and mackerel prey to such an extent on the animal plankton, and that the bottom life in these regions is poor compared with that in northern waters. Thus more food is available for the plankton-eating invertebrates. The corals are night feeders and there is an enormous plankton life at night in this vicinity. The inference is that the planktonic life is sufficient to support the corals.

Science News a Century Ago

The Entomological Society

AT a meeting of the Entomological Society held on August 3, 1835, Mr. J. F. Stephens (1792–1852) being in the chair, "Various curious and remarkable insects were exhibited, amongst them the Indian leaf insect (*Phillium siccifolium*) in its different stages, from the collection of Mr. Saunders. A living capricorn beetle was exhibited by Mr. Desvignes, which had been reared in a piece of furniture nearly ten years old. Specimens of the vegetation wasp, horse tick, spider silk, etc., from the island of St. Domingo were exhibited by Mr. Hearne. The chairman also exhibited a specimen of the very rare and singular bee parasite, *Elenchus tenuicornis* Kirby, recently captured by himself, and made some observations on its peculiarities."

"The memoirs read consisted of a note upon the insects found in unrolling a mummy at Belfast, by Mr. Patterson, president of the Natural History Society of that city; an account of the *Poma Sodomitica*, or Dead Sea apples, a production respecting which travellers and botanists have been greatly at issue, but which has lately been ascertained to be a vegetable gall of a very large size, by Walter Elliot, Esq., by whom these productions were discovered growing in Palestine, and who has reared the insects which produce them". (*Athenaeum.*)

Experiments with the Lime Light

ON August 5, 1835, *The Times* gave an account of the experiments with the limelight made on the top of the Colosseum in London by Mr. Alexander Gordon. Gordon employed four jets of oxy-hydrogen gas impinging on a cylinder of lime and an arrangement of lenses which caused the light to pass out in a sheet or fan. "It is a very simple, though excellent invention, and appears capable of being applied to lighthouses and similar buildings with great efficacy. . . ."

Reappearance of Halley's Comet

No astronomical event of 1835 was looked forward to with greater interest than the reappearance of Halley's comet, last seen in 1759. As early as 1817, its motion and perturbations since 1759 were proposed by the Turin Academy of Sciences as a subject for a prize, which was awarded to Baron Damoiseau. The Paris Academy of Sciences adjudged a similar reward to Pontécoulant in 1829, while Rosenberger's calculations won for him the Gold Medal of the Royal Astronomical Society. The comet was first seen on August 6, 1835, by the astronomers at the Jesuits' College at Rome as "a nearly circular misty object" and it was afterwards watched by astronomers in various countries. The error of Rosenberger's ephemeris was only seven minutes of arc, and the perihelion passage took place on November 16, five days after the predicted time. Owing to its southern declination, it was seen to greatest advantage at the Cape of Good Hope by Maclear and Sir John Herschel, who continued to observe it until May 5, 1836, when it finally ceased to be visible. Reviewing the calculations made regarding the comet, Grant said: "The fidelity with which it responded to the deductions of the geometer on the occasion of its last appearance forms one of the many magnificent triumphs which adorn the history of the Theory of Gravitation".

The British Association at Dublin

THE Dublin correspondent of *The Times*, writing on August 7, 1835, said: "A considerable number of distinguished literary visitors are already in this city, for the purpose of attending the meetings of the British Association, which commence on Monday. The *William Penn*, from Liverpool, with a great many more, is expected at Kingstown this evening. Many curiosities are looked for during this eventful week in Dublin; but Lord Brougham is expected as the 'great lion'. I am sure his Lordship will feel quite at home in Ireland". Writing again on August 9, the correspondent said: "Up to 5 o'clock yesterday evening the council of the Association was occupied with the admission of members. Mr. Thomas Moore, accompanied by Dr. Lardner, arrived in town yesterday. On Friday evening the *William Penn* reached Kingstown from Liverpool, freighted with scientific visitors amongst whom were Dr. Babbage and Sir John Ross. The same vessel is expected this evening with a similar cargo. There are several foreigners in town as delegates from various parts of the continent. Many are the 'lions' we have already, but alas! Lord Brougham is not to be amongst us, and the lovers of curiosities are mortified accordingly".

Societies and Academies

EDINBURGH

Royal Society, July 1. ALAN W. MOZLEY: The freshwater and terrestrial mollusca of Northern Asia: A critical and detailed study of sixty-seven species and sub-species of non-marine mollusca from Siberia, fifty being aquatic and seventeen terrestrial. They are of four categories: (i) those common to Europe and Asia; (ii) those that are circumboreal: (iii) those common to north-east Asia; and (iv) those endemic to Siberia. The various habitats are described. From the point of view of molluscan distribution, four faunal regions are recognised: (i) the great Siberian region; (ii) the Baikal region (this is rich but so peculiar and specialised that it falls outside the scope of the present paper); (iii) the far eastern region; and (iv) the Chuckchee-Kamchatka peninsula. S. M. K. HENDERSON: Ordovician submarine disturbances in the Girvan district. The Ardwell Beds, a series of greywackes of Lower Caradoc age in the Girvan district of Ayrshire, contain intraformational breccias and slip-bedding; grading, with accompanying minor current bedding, is common throughout. The disturbed bands rarely exceed three inches and show an eroded upper surface, especially clear in examples of slipping. In the case of breccias, submarine earthquakes loosened and broke up the sea floor sediment; resultant tunamis tore up and distributed the debris. Sediments of a more plastic nature slid down submarine slopes. A boulder bed has likewise been attributed to the slipping of sediment down a submarine slope. MARY G. CALDER: Further observations on the genus *Lyginorachis*, Kidston. Three new species of the fossil genus *Lyginorachis* are described, namely, *L. Waltoni*, *L. Brownii* and *L. trinervis*. The specimens are all from rocks of Calciferous Sandstone age in the west of Scotland, *L. Waltoni* being from Arran and *L. Brownii* and *L. trinervis* from the Kilpatrick Hills. Some additional notes are also made on *Lyginorachis taitiana*, from specimens in the Kidston Collection of Fossil Plant Slides. STEWART MACLAGAN and EDWARD DUNN: The experimental analysis of the growth of an insect-population. Experiments with the rice weevil (*C. oryzæ*) have shown that a population of these beetles offers a certain internal resistance to its own growth. This is effected through a decrease in the copulation frequency, fecundity and fertility of the adults, with increasing density; and an increase in larval mortality. The behaviour of the beetles is entirely irrational, the limitation of population growth being brought about by influences which are primarily thigmotropic. So precise is the relationship between the population density and the copulation frequency of the beetles that it can be described by the equation $Y = aX^{-b}$, where Y represents copulation frequency and X the population density (see also NATURE, Jan. 5, p. 33). T. M. MACROBERT: Some series and integrals involving associated Legendre functions, regarded as functions of their degrees. Legendre functions and products of Legendre functions in finite integrals and series are replaced by the corresponding Mehler-Dirichlet integrals; the resulting formulæ are then expressed as Dirichlet integrals, and the limits of these integrals give the values of infinite integrals and series.

PAUC: The resolution of abstract equations by a method of iteration. FRÉDÉRIC ROGER: The relation between the tangential and metric properties of certain sub-ensembles of Jordan curves. JEAN FAVARD: The polynomials of Tchebicheff. D. MICHNEVITCH: Functional groups and their applications. GEORGES VRANCEANU: The unitary theory of fields and non-holonome hypersurfaces. PIERRE VERNOTTE: Sketch of a theory of reactivity. BENJAMIN DE JEKHOWSKY: The number of asteroids and their effective mass. FRANÇOIS LINK: The eclipses of the satellites of Jupiter. D. G. DERVICHIAN: Correction to the constant of Eötvös reducing it to two distinct values. JEAN URBANEK: Form and symmetry of the electromagnetic equations: the equivalence of energy and mass. EMILE SEVIN: The levels of the neutron. PIERRE MESNAGE: The molecular emission spectra of some metallic salts. The spectra produced by the high-frequency discharge without electrodes were studied in the cases of silver chloride, zinc chloride and nickel chloride. RENÉ BERNARD: Production of the Vegard-Kaplan bands by the electronic bombardment of a mixture of argon and nitrogen. The spectrum as a whole showed a striking analogy with that of the night sky, owing to the presence of the Vegard-Kaplan bands. CASIMIR JAUSSERAN: The action of aqueous solutions on latent photographic images of different ages. MME. IRÈNE CURIE, HANS VON HALBAN, JR. and PIERRE PREISWERK: The radioactive elements formed during the irradiation of thorium by neutrons. One of the elements produced is an isotope of radium, another is an isotope of protactinium. HENRI MULLER: Hydrofluoric acid. WILFRIED HELLER: The spontaneous formation of definitely arranged aggregates in sols containing non-spherical particles. JULES GUÉRON and MARCEL

PRETTRE: The complexity of the reaction between ozone and potassium iodide. When ozone acts on potassium iodide, two reactions occur simultaneously, one giving iodine, the other iodate. PIERRE CARRÉ and DAVID LIBERMANN: The alkyl- and aryl-sulphinic esters. RENÉ RAMBAUD: The action of sodium ethylate on the γ-halocrotonic esters. JEAN JUNG: The recrystallisation of the diorites and quartz diorites of the Manson (Puy-de-Dôme) plateau under the influence of granite contact metamorphism. STOYAN PAVLOVITCH: The amphibolites of the Zlatibor massif (western Serbia). GEORGES DENIZOT: The tectonic of the massif of Allauch, near Marseilles. GEORGES CORROY: The bases of the Jurassic link of Roqueforcade-Nans to the north-west of Sainte-Baume. GEORGES CLAUZADE: The bases of the link of Roussargue-Liquette, to the west of Sainte-Baume. PAUL DELEAU: The presence of the Lias at Djebel Nador (Department of Oran). JEAN DRESCH: The structure of the Haouz of Marrakech. J. LACOSTE and C. BOIS: Remarks concerning the first movements of the soil during earthquakes affecting some European regions. ADOLPHE LEPAPE and GEORGES COLANGE: The presence of water vapour and carbon dioxide in the air of the stratosphere. The proportions of moisture and carbon dioxide in the air of the stratosphere, altitude 9–16 kilometres, is unexpectedly high. The carbon dioxide is about double that found at the surface, and the moisture much higher than corresponds to the temperature. CAMILLE ARAMBOURG: Observations on some fossil fishes of the order Halecostomes and on the origin of the Clupeids. MARCEL ABELOOS: The larval diapause and eclosion in the Coleoptera *Timarcha tenebricosa*. JEAN GIAJA and STEFAN GELINEO: The resistance of some homeotherms to low temperatures. Various animals and birds were submitted to temperatures ranging from − 35° C. to − 160° C., for short periods without injury. A dog after remaining in a chamber for five hours at − 160° C. was uninjured. HENRI BIERRY and BERNARD GOUZON: The fluorescence spectra of [illegible] flavin before and after irradiation. ETIENNE WOLFF and ALBERT GINGLINGER: The experimental production of intermediate sex forms by the injection of folliculin in the embryo of the fowl. In the embryo of the fowl intersexuality can be regularly obtained by injecting genetically male individuals with folliculin, on condition that the injections be made before the seventh day and the dose about 100 international units. VICTOR PLOUVIER: Contribution to research on amygdonitrileglucoside and amygdoside in plants. YERVANTE MANOUELIAN: Experimental syphilis. Lymphatic ganglia. Minute forms of *Spirochæta pallida*, syphilitic spirochætogen. LEDOUX-LEBARD, LONG and SAGET: Radioscopic examination in a lighted room.

MELBOURNE

Royal Society of Victoria, May 9. LEO STACH: Victorian Tertiary Catenicellidæ (Bryozoa), (3). This paper concludes a study of the systematics of the Tertiary Catenicellidæ, with a revision of members of the sub-families Catenicellinæ and Ditaxiporinæ. Notes on Scuticellinid gonœcia, the species incorrectly relegated to Catenicellidæ, and extra-Australian Tertiary species, are appended. A new genus, *Chelidozoum*, of the family Savignyellidæ is erected for *Claviporella vespertilio*, Macgillivray.

WASHINGTON, D.C.

National Academy of Sciences (*Proc.*, **21**, 235–299, May 15). H. C. SHERMAN and H. L. CAMPBELL: Rate of growth and length of life. Rats of the same heredity, initially in good health, living in the same environment and subsisting on one or other of two normal diets, both of which were adequate to maintain growth and health although one was better balanced quantitatively, show different rates of growth, those on the better diet growing faster. Growth rate and length of life, however, vary independently of one another. CHARLES E. DECKER: The graptolites of the Simpson group of Oklahoma. VIRGINIA H. RHOADES: The location of a gene for disease resistance in maize. Plants susceptible to physiological form 3 of *Puccinia Sorghi* were pollinated with material from a plant, homogeneous for the dominant factor for resistance, which had been irradiated with X-rays. Irradiation produces a chromosomal deficiency, and in susceptible offspring, the deficiency appeared in the short arm of the tenth and shortest chromosome of the haploid complement. Breeding experiments confirmed this finding. FRANK H. CLARK: Linkage relations in 'Zavadskaia shaker' in the house mouse (*Mus musculus*). This character is distinct from and is not linked with the characters 'ordinary shaker' and 'waltzing'. Linkage tests suggest that it is located in chromosome 14; and possibly the gene for hydrocephalus lies in the same chromosome. DONALD L. WEBB: Generation of any n-valued logic by one binary operation. W. E. SEWELL: Generalised derivatives and approximation. MARSTON MORSE and GEORGE B. VAN SCHAACK: Abstract critical sets. CHARLES N. MOORE: On convergence factors for series summable by Nörlund means. EDWARD V. HUNTINGTON: Effective equality and effective implication in formal logic. S. LEFSCHETZ: A theorem on extremals (1). ALONZO CHURCH: A proof of freedom from contradiction. JENNY E. ROSENTHAL: Intensities of vibration rotation bands. A theoretical discussion in which an exact expression for the probability of any transition $v' \leftarrow v''$ is derived for the case of a Morse potential function between the nuclei. It gives results in good agreement with experimental values for HCl. G. H. PARKER: What are the resting and the active states of chromatophores? The chromatophore systems of different animals are very differently organised so far as nerves are concerned, but all appear to be subject to neurohumoral control. Experiments on *Fundulus* in which bands across the tail were completely denervated by section of the nerves, showed that the melanophores of these bands were still active. It is concluded that pigment immobility in a melanophore defines the resting state. Brownian movement is greatly reduced in such a state, suggesting that the active and resting phases are characterised by the protoplasm of the melanophore being in the sol and gel states respectively. J. VAN OVERBEEK: The growth hormone and the dwarf type of growth in corn. The dwarf type *nana* differs from the normal race by a single gene. Coleoptiles are equal in length, but the mesocotyl of *nana* is shorter than the normal, due to decreased extension. Less growth substance (auxin) is given off by *nana* than normal corn, and less growth occurs for a given amount of auxin. It is concluded that more auxin is destroyed in *nana*, due to a change in oxidation-reduction properties, thus causing inhibition of growth.

Forthcoming Events

The Future of British Agriculture

AT a time like the present, when radical changes are taking place or being contemplated in our national economy, when countries like Great Britain, Holland and Denmark are abandoning the policy of Free Trade and venturing on the thorny paths of Protection and national self-sufficiency, efforts to discern the future acquire an interest and importance that far outweigh the vaticinations of those who don the prophet's mantle in more settled and humdrum times. History, we know, is replete with the misjudgments and miscalculations of statesmen and politicians who, besides having to deal with the incalculable in human nature, have also been [illegible] lack of scientific training and to help [illegible]ok; and the question is now frequently [illegible] whether men trained in the methods and [illegible]ject matter of science could not do better? So far, the [illegible] have seldom been called upon to act, or [illegible]larly [illegible] advised on the affairs of State; and it is made [illegible]ain that had they been asked, they would [illegible] 100 [illegible]n more successful than their contemporary [illegible]tributi[illegible]n, trained in the law, the humanities or [illegible] amygdala. Experiments. Are the views of scientifically trained [illegible] forms [illegible] political, economic, social, religious and [illegible] LEDOUX [illegible]tical questions more far-sighted, more [illegible] examin[illegible]d and less biased by traditional beliefs and [illegible]a[illegible] prejudices than those of others?

Roya[illegible] [illegible]e[illegible]t a general vote on this question would result in [illegible] decided 'No': and the main reasons for the answer would be that the scientific mind, like the artistic, generally runs in grooves, and the [illegible] that are applied so fruitfully in the positive [illegible]es are either not applied, or if used are misapplied, in those spheres which to a large and regrettable extent are still dominated by instinct and desire rather than by reason and the public good. Although the doctrine that mental ability acquired in one sphere is not transferable to another unless the subject matter is correlated, seems to apply here, a case can be made out that scientific habits of mind, such as initial doubt, careful testing of fundamental assumptions and evaluation of evidence, do come within the category of transferable qualities. If this is so, it affords an additional reason why those engaged in scientific pursuits should seek to pull their weight in the social boat by using their talents in trying to solve some of the pressing social and economic questions that now await solution.

Prediction, based upon generalised knowledge of natural facts, is one of the major, and perhaps the most useful of the functions of science: we know how well it succeeds in the strictly mathematical sciences and in certain applied sciences like astronomy and engineering, but in agriculture, which is a congeries of applied sciences still largely dominated by tradition and empiricism, prediction is far more difficult; there are so many variables; the weather and the human factor between them upset many a calculation. Some measure of sympathy must therefore be extended to Sir John Russell, who, in his recent discourse at the Royal Institution on the future of British agriculture, set himself a very difficult task. Many eminent persons, he remarked, had lost their well-earned reputations by dabbling in the future, but in these critical times, one had to take risks; and the safer method was to base one's predictions on present trends and movements.

Among the unchanging elements in our agricultural economy, Sir John Russell mentioned the present regional distribution of crops, which is determined largely by climate and soil; it is,

however, an interesting fact that all our crops, excepting sugar-beet, hops and lucerne, are grown in every county, and it seems to us quite possible that efficiency in production and distribution might be increased by introducing some measure of rationalisation. According to free-trade principles, each country should grow what it is best fitted to grow, and exchange its excess for foreign products which it wants. Might not the same principle be applied to regions within a country? And is it not time to contemplate the subdivision of the country into regions that would take the place of the counties, many of which are very small and some minute, and in this way save expenditure on administration? We may yet live to see established a modern form of the old Anglo-Saxon heptarchy.

The sturdy, independent and strongly individualistic character of the English farmer will, Sir John suggested, remain as a bulwark against collectivist tendencies in the population, and that is to the good, because State supervision failed during the late War: it failed in France in the Revolution, and it is proving a failure in Russia now. Further, the English countryman's attachment to animals (however fond he may be of killing them!) will ensure that the production of animals and milk will continue to form the major part of his occupation; he is also likely to retain his love of craftsmanship and his dislike of mass production methods. Thanks to the development of agricultural education, there is arising a generation of farmers who are keener, more alert and more anxious to make the best of their farms than were their predecessors.

Implied in Sir John Russell's prognostications is the improbability of any really fundamental changes taking place in our political and economic structure. Our present individual farming, he holds, will persist, and continue to be of the small capitalist type that now occupies about one half of our farm-holdings with an area varying from 100 to 300 acres. There is, however, a prominent school of agricultural thought, of which Mr. C. S. Orwin, of the University of Oxford, is an able exponent, which believes that nationalisation of the land will follow as a direct consequence of our present parlous agricultural conditions. The old partnership relations of landlord and tenant have disappeared; the landlord has lost most of his capital and can no longer undertake the duties which that partnership imposed upon him. The land is crying out for fresh capital—for drainage, water supplies, farm equipment and housing—and if the changes which this school sees coming are brought about, namely, an increase in family-farms on one hand, and in large-scale, mechanised and specialised farms on the other, the call for new capital will be greater than ever. As an economic necessity, the State must take over the land, provide the necessary capital, but not necessarily control the farming practice.

It is not always realised that the vast majority of the world's farming is done by the peasant class—small men with little or no capital, whose standard of living is low compared with that of industrial workers, who are gluttons for work, and to whom agriculture is a mode of life rather than a money-making occupation. Although this type of farming cannot as a rule compare in economy and efficiency with the large-scale mechanised type, nevertheless it is encouraged by practically all Governments, because it represents an element of stability in the State: family-farmers are [illegible] supporting in times of depression and they [illegible] stitute a reserve of man-power in time of [illegible]. Even highly industrialised nations like [illegible] Britain have been constrained to encourag[illegible] type, though not always with succes[illegible]. In connexion, Sir John Russell points out th[illegible] main difficulties are concerned with mar[illegible] and leadership, and he does not believe that we should succeed in establishing co-operative colonies of smallholders on the highly s[illegible] Denmark; he envisages rathe[illegible] settlement, self-contained and [illegible] which living, not selling, is t[illegible] unit producing what it can and b[illegible] for commodities it does not [illegible]. experiments of this kind are [illegible] England; they have been suc[illegible] Canada, in other parts of the Br[illegible] in the United States, but in nea[illegible] settlers have been drawn togeth[illegible] a spiritual bond, such as the Ch[illegible].

The factory type of farming, [illegible] mechanisation of agricultural [illegible] specialisation in the growing of [illegible] crops, is obviously the more e[illegible] and horse labour, but is not of [illegible] cation. Sir John Russell state[illegible] system of English farming r[illegible] manent employees per square [illegible] a highly mechanised farm [illegible] one man per square mile suffices. Th[illegible] for the development of factory farms and of

small holdings has been ably expounded by Mr. C. S. Orwin in his book on "The Future of Farming" (Oxford University Press, 1930), but his conclusions appear to be in direct opposition to Sir John Russell's prediction that the medium-sized farm owned by the small capitalist will continue to prevail in Great Britain.

If it cannot be admitted that British agriculture has grown and developed continuously from very early times, progress was catalysed by the coming of the industrial era and the fear of starvation during the Napoleonic wars. The growing of turnips, clover and rotation grasses, which did not become general until more than a hundred years after the idea had been introduced from Flanders; the improvements in livestock due to Bakewell, the brothers Colling, Thomas Bates and others; and later the use of artificial fertilisers and the breeding of new varieties and strains of economic plants, have all contributed their quotas to the great increases in [illegible]roduction that were rendered necessary by [illegible]emendous growth in population. As in industry, [illegible]e problem of production seems very largely to [illegible]ve been solved; the most urgent problems now [illegible] those of distribution and quality of product.

[illegible]n Great Britain, however, the problem of in-[illegible]ased production is still with us, for owing to greatly reduced income from the export of goods and services and investments overseas, not to mention possible international complications, [illegible] is now generally agreed that we must [illegible]d at home. Sir John Russell agrees [illegible]nt output of 36–40 per cent of the [illegible]upply is too low, and he asks for an [illegible]y to be conducted by technical and [illegible]erts, and representatives of the [illegible]griculture, the Foreign, Colonial and [illegible]fices, who would advise where the [illegible] drawn. A question embodying this [illegible]tion was asked in the House of [illegible]uly 15, when the Minister of Agri-[illegible] that it was not acceptable, but the [illegible]as fully alive to the question of [illegible]uction of food in relation both to [illegible] of agriculture and to the general [illegible]e country. It would appear that [illegible]nister and the Cabinet are not [illegible] deliberate long-term planning; [illegible]al quiver seems to be fully charged [illegible]ate and delicate problems associated [illegible]king of the various marketing boards, [illegible] launched with the entirely praise-worthy object of securing an economic return to the producer. In Sir John Russell's view, the ordered development of British agriculture involves deciding how much should be produced at home; and he favours the contract system, with obligations on both sides, including the social obligation of paying a living wage to the workers. That system works well for milk, sugar-beet and bacon, but it is not applicable to produce like beef, mutton, potatoes, eggs, which are handled by a multitude of small distributors. The problem of distribution, it is generally conceded, is of outstanding importance, and no Government that does not tackle it resolutely and impartially is worthy of our support.

The history of British agriculture shows that although men of enlightenment have seldom been lacking, progress has usually been extremely slow, owing to the crusted conservatism of the farming population. In the last hundred years, science has done wonders in giving the farmer the means to increase production, but although he has used them to some extent, the potentialities, especially of fertilisers and of scientific breeding, still remain very great. In the past, the greatest spur to progress has always been economic necessity, and as this is now again in the ascendant, it seems probable that, at any rate in the near future, changes in our economic system generally are likely to play a greater part than the application of new scientific discoveries. When we reflect that about one quarter of our population is living to-day on or under the border-line of poverty, that the average income of 75 per cent of our insured workers is £3 a week or less, and that about 70 per cent of those who died in 1933–34 left no more than £100, or less, we cannot be surprised at the economic unrest that obtains in so many quarters. Until some solution or amelioration of the problem of the existence of poverty amidst plenty is forthcoming, substantial national progress seems out of the question.

The Chancellor of the Exchequer may derive satisfaction from the statement that "we" have recovered 80 per cent of our prosperity, and that "we meet in an atmosphere of such happiness and contentment as has not been seen since the War" (as he told the bankers in a recent post-prandial speech), but such assertions do not help the cause of social peace and development; rather do they, by substituting illusion and self-satisfaction for ascertainable fact and self-suppression, reflect an attitude of mind which is the negation of the realistic spirit of all true science.

The Oldest European Civilisation

The Palace of Minos:
a Comparative Account of the Successive Stages of the Early Cretan Civilization as illustrated by the Discoveries of Knossos. By Sir Arthur Evans. Vol. 4, Part 1: Emergence of Outer Western Enceinte, with New Illustrations, Artistic and Religious, of the Middle Minoan Phase; Chryselephantine 'Lady of Sports', 'Snake Room' and Full Story of the Cult; Late Minoan Ceramic Evolution and 'Palace Style'. Pp. xxxv+378+14 plates. Vol. 4, Part 2: 'Camp-Stool' Fresco—Long-robed Priests and Beneficent Genii; Chryselephantine Boy-God and Ritual Hair-Offering; Intaglio Types, M.M.III–L.M.II; Late Hoards of Sealings; Deposits of Inscribed Tablets and the Palace Stores; Linear Script B and its Mainland Extension; Closing Palatial Phase—'Room of Throne' and Final Catastrophe; with Epilogue on the Discovery of 'Ring of Minos' and 'Temple Tomb'. Pp. xvi+379–1018+22 plates. (London: Macmillan and Co., Ltd., 1935.) 2 parts, £9 9*s*. 0*d*. net.

THE fourth volume, in two parts, of "The Palace of Minos" completes what is the most remarkable account of an archæological site ever published, and it appears just forty years after Sir Arthur Evans began his first exploration at Knossos. The whole work, to use the author's own words, "has some title to be regarded as an Encyclopaedia of Minoan cultural features, of its Art, and of its Religion". These two parts run to 1,069 pages, with 966 figures in the text and 36 plates, and from this comprehensive material a reviewer can only select for comment some of the more remarkable matters here brought to light as illustrative of Minoan religion, art and civilisation.

We begin with the most recent additions to our knowledge of Minoan religion. In a private house adjoining the palace, there was found stored in a large jar a collection of objects belonging to a domestic snake cult. These articles included 'snake-tubes', large cylindrical vessels up which the snakes could climb to drink from little cups attached to the sides of the tubes, and a tripod 'snake table', the upper surface of which is divided into four separate compartments and has in the centre a base for a bowl to contain food for four snakes. Sir Arthur cites numerous parallels from other ages and regions of similar cults of domestic snakes (p. 138 ff.). The ring-snake, *Tropidonotus natrix*, still common on the site of Knossos, is apparently the species which was the special object of Minoan veneration and affection. Besides this, another snake is thought to have had influence of a different kind, its skin supplying a pattern, the 'wave and dot' motive, which is common in Minoan art. This is the cat-snake, *Tarbophis vivax*, which has markings rather like those of the adder. The author traces the spread of this pattern west to Etruria, where the snake was likewise an object of veneration and fear (p. 178 ff.). Like much else in Greek religion, the snake cults associated with Athena, Asklepios, dead heroes and ancestors had their Minoan precursors.

The custom familiar from classical Greece of the ceremonial cutting off of childhood's locks at puberty is another religious usage that is shown to have had a Minoan origin (p. 475 ff.). The exquisite ivory figurine of a boy, now illustrated for the first time, has his hair shorn off over the whole crown and is thought to have worn a skull-cap of thin gold upon his pate. This has led Sir Arthur to revise his view about some plaited locks carved in steatite found in a domestic sanctuary, and he now regards them as simply votive, comparing them with a Thessalian monument representing locks of votive hair.

In the sphere of art, this volume presents us with accounts and illustrations of some of the most admirable works of the Minoans. The ivory figure of the tonsured boy, already mentioned, is one of these; and it is interesting to be able to compare him with the other ivory 'boy-god', discussed by the author in a former volume, but here illustrated anew (p. 468 ff.). Both these little statuettes, typically Minoan as they are, surprise and delight by their astonishing realism. It is because the Minoan had little of the liking for such metrical formalism as appealed to the early Greek artist that these Cretan works of art often seem more akin to the fourth century B.C. than to the age of archaic art. What is perhaps the finest Cretan masterpiece yet discovered—finer even than the famous Boston ivory goddess—appears on the frontispiece of the first of these two volumes. It is the gold and ivory figure of a girl dressed for the Minoan bull-ring. It is now in the Toronto Museum. Sir Arthur Evans calls her "our Lady of Sports", regarding her as the Minoan goddess herself in the dress of one of her protégés, the taureadors of those days. Another work of a very high order is a gold pendant in the form of two bees or hornets symmetrically grouped with a ball and a granulated disc between

them (p. 75). This ornament, dating back to about the twenty-third century B.C., is one of the finest extant examples of the goldsmith's art. For the rest, many charming art miniatures are illustrated among the engraved stones, rings and sealings which are fully discussed in these volumes.

It is, however, the evidence for the high degree of Minoan civilisation that always fills the present generation with admiration and wonder. Earlier volumes have familiarised us with the efficiency of Knossian sanitation, and here we have something more about the well-designed drain-pipes and the carefully made refuse-pits for dumping rubbish. We glean in passing that Minoans may have held cattle-shows, that they were meticulous in their business methods, that the palace magazines could store as much as 16,800 gallons of oil. They used camp-stools, their women were lavish in the employment of 'make-up', and as early as the fifteenth century before our era they were wearing gloves. Towards the end of the volume, there is a full account of Minoan script, for which the Oxford University Press has now a fount. Numerals can be read, the gist of some of the writings can be grasped; but until a bilingual text turns up we cannot read the language that Minos spoke.

How did this great civilisation come to an end? It has usually been held that a piratical raid, perhaps of 'Achæans' from the Greek mainland, destroyed the Cretan palaces with fire and sword. Sir Arthur Evans puts forward the suggestion that an earthquake, more serious than many that had occurred before on this shock-ridden site, shattered the palace, which was partly gutted, and that the Minoan dynasty removed the seat of Government to some healthier spot. There was, at any rate, a persistent tradition in classical times that Minos met his end in Sicily (p. 959 ff.).

The oldest civilisation in Europe is set before us in a strangely vivid fashion by the author's discoveries. This work is literally 'epoch-making', because Sir Arthur has supplied the epochs for European prehistory; but he has done more, because he has made the Minoan Cretans live for us. He has pictured a race bound to sacerdotalism and haunted by the supernatural, a people whose art like their culture was sometimes superficial. Yet they prepared the way for the civilisation of the Greeks and consequently for our own. We can look back and say that poetry, history, philosophy and science might not have arisen in the world but for those early and successful attempts of the Minoans to build an ordered and civilised society.

C. T. S.

Vibration in Engineering

(1) Practical Solution of Torsional Vibration Problems:
with Examples from Marine, Electrical and Automobile Engineering Practice. By W. Ker Wilson. Pp. xviii+438. (London: Chapman and Hall, Ltd., 1935.) 25*s*. net.

(2) Torsional Vibration:
Elementary Theory and Design Calculations. By W. A. Tuplin. Pp. xviii+320. (London: Chapman and Hall, Ltd., 1934.) 21*s*. net.

(3) The Theory of Vibrations for Engineers:
an Intermediate Course. By E. B. Cole. Pp. x+263. (London: Crosby Lockwood and Son, Ltd., 1935.) 15*s*. net.

THE theory of vibrations has in recent years become of dominating importance in engineering. It is well known, for example, that vibrations in heavy machinery may be of a destructive nature, causing failures in the machines themselves and having damaging effects upon surrounding structures. The growing importance of the subject is leading to a considerable output of research but, although a number of books have been published in other countries, especially Germany, there has been until now no reasonably complete exposition in English of the more recent work on the torsional vibrations of shafts.

(1 and 2) Mr. Ker Wilson and Mr. Tuplin have each devoted a complete book to this important division of the subject of vibrations, and have discussed the applications of the theory to the design of multi-cylinder engines. Mr. Wilson, in a book of more than 400 pages, has been able to give a very thorough account, with numerous practical examples, many drawn from marine engine design. He also devotes a great deal of space to the theory and design of damping devices and to instruments for the measurement of vibration amplitudes. His work should prove of great service to many practising engineers.

Mr. Tuplin's treatise includes very full details of practical methods as well as much general theory. His book is shorter than Mr. Wilson's but, in the space at his disposal, he has included a surprisingly large amount of

material without giving any impression of crowding or undue abbreviation. Except that he does not discuss measuring devices, he deals with nearly all the subject matter of the larger book and he includes a number of fully worked practical examples. Many of his methods differ from Mr. Wilson's, and the two books should be regarded as mutually complementary rather than as alternatives.

(3) Mr. Cole's book is of a different nature, being an introductory textbook on the general theory of those parts of the subject of vibrations that are important to engineers. The theories of free vibrations, with and without damping, and of forced vibrations are first dealt with. Engine vibrations, the elimination of vibration, the transverse vibrations of beams, and the whirling of shafts are then briefly discussed. The exposition is throughout very clear and is helped by a large number of excellent figures. Examples for practice are added at the ends of the principal sections, the answers being given. All engineering students with any mathematical ability would profit by using this book as a supplement to the chapters on vibrations in their textbooks of strength of materials and theory of machines, and many mature engineers might find it of value as an introduction to more specialised treatises and original papers.

The Reptiles of China

The Reptiles of China: Turtles, Crocodilians, Snakes, Lizards. By Clifford H. Pope. (Central Asiatic Expeditions: Natural History of Central Asia, Vol. 10.) Pp. lii+604+27 plates. (New York: American Museum of Natural History and G. P. Putnam's Sons; London: G. P. Putnam's Sons, 1935.) 10 dollars.

MR. POPE'S "Reptiles of China" is the outcome of some fourteen years of continuous study. Four of these were spent in the field collecting and observing, the remainder in a more detailed study of his material in New York, and a comparison of it with the collections already existing in the other great museums of the world. No complete survey of this large area has been attempted before, and herpetologists will be grateful to Mr. Pope for having collected, examined and arranged the mass of material and literature relating to the subject which is now available.

The area dealt with is China south of a line connecting the northern extremity of the Gulf of Liaotung with the northernmost point of Kansu Province. This, although the author does not say so, is, roughly speaking, China south of the Great Wall, together with the eastern part of Tibet; the Island of Hainan is included but not Formosa. The bulk of the volume, pp. 19–453, is given up to the account of the Chelonians (22 species), the Crocodilians (1 species) and Snakes (130 species and subspecies); while the Lizards (65 species, pp. 457–487) are condensed into an annotated check list, with keys for their identification.

The descriptions, although short, are generally sufficient for their purpose. For the first time in any large textbook, we have details of the sexual variation in snakes and of their penial characters. That the latter have considerable specific value cannot now be doubted, although their full taxonomic importance can only be assessed when we have a wider knowledge of them. Habits also, in so far as they are known, are fully recorded. The field-naturalist will welcome these, but to the museum worker they have also a value, although at present he is inclined to ignore them. The mental 'make-up' of reptiles, as shown by their mode of life, has scarcely yet been studied, but it is evident that certain habits are confined to certain groups and, in their way, are as distinctive of the group as morphological characters. When they can be properly interpreted and correlated, they will have a significance which the taxonomist cannot afford to ignore.

On the other hand, the descriptions as regards external morphological characters, particularly those relating to the generic diagnoses, appear sometimes too brief. This is a pity, for a work of this magnitude, although intended primarily as a means of identifying the species, would have been so much more valuable had it included also that general anatomy which forms the basis of our classification and upon which the identifications depend. Without a knowledge of the generic characters also, it will be difficult sometimes to place a species new to science, or one new to the country and not mentioned in the work.

The volume is well illustrated; most of the text figures are new. There is a map, and a list of localities where collections have been made; these are all properly fixed as regards their geographical positions, a very necessary procedure for a region that is so little known. The bibliography includes all the available literature up to 1934. Mr. Pope has spared no pains to make his work as complete as possible; he is to be heartily congratulated on the result.

M. A. S.

A Manual of the Principles of Meteorology

By R. Mountford Deeley. Pp. xi+285+4 plates. (London: Charles Griffin and Co., Ltd., 1935.) 15*s.* net.

THIS is not a manual so much as a criticism of the present science of meteorology. The author points out that the distribution of temperature in the lowest six miles or so of the atmosphere—the troposphere—does not fit the pressure distribution, the lowest pressures occurring in high latitudes where the air is coldest. Differences of pressure on the earth's surface must therefore be caused by differences of temperature at high levels in the stratosphere, which is relatively warm in high latitudes and over barometric depressions, and relatively cold in low latitudes and over anticyclones. His thesis is that this high-level heating is caused by corpuscular radiation from the sun; the main stream of corpuscles is directed by the earth's magnetism into two sub-polar rings which therefore form belts of low pressure, while local barometric depressions originate from stray streams of corpuscles.

The main support for this theory is found in a series of diagrams comparing the mean daily pressures and ranges of pressure over the North Atlantic with daily sunspot numbers, which show some general resemblances (and also many discrepancies), but the author also considers that variations of corpuscular radiation explain the great climatic changes of geological time.

The style is discursive and often obscure, while there are many small errors and some serious omissions. For example, there is only the barest reference to the Bjerknes theory of cyclones and no mention at all of the 'polar front' or of Simpson's well-known theory of the part played by variations of solar radiation in climatic changes. The get-up is good on the whole, but the isothermal maps are poor.

Leçons de zoologie: Annélides

Par Prof. M. Prenant. (Actualités scientifiques et industrielles, 196.) Pp. 95. (Paris: Hermann et Cie, 1935.) 16 francs.

THE author has selected his material judiciously so as to give the reader an account of the principal structural and biological features of annelids. Brief descriptions of *Polygordius* and of its trochosphere larva, of *Nereis* as a type of the Polychæta, and of the principal variations in parapodia and in a few other structural features precede the classification and the two pages devoted to the ecology of marine worms. A more summary consideration follows of the Oligochæta, Hirudinea, Myzostomida and Echiurida, the last giving the opportunity for observations on the determination of sex in *Bonellia*. The comparative account of the excretory organs and the chapters on regeneration and asexual reproduction, often with accompanying changes of form, for example, in *Heteronereis*, are of particular interest. The figure of a trochosphere of *Echiurus* showing a segmented mesoderm is incorrectly attributed to Baltzer, who stated that the mesoderm is unsegmented.

Problèmes actuels de l'astrophysique

Par Prof. L. Houllevigue. Pp. xii+268. (Paris: Armand Colin, 1935.) 14 francs.

IN this volume Prof. Houllevigue gives an interesting and chatty account of many of the points at which the astronomer of to-day is touching upon the palpably unknown. It is interesting to see not only the selection of problems made by the author but also the way in which these problems are envisaged by a Frenchman. To take one example of his special point of view, the chief emphasis in his account of recent and coming advances in telescopes is placed upon the Ritchey-Chrétien researches, whereas most people would deal with the 200-inch telescope now being constructed for California. Among the twenty-five subjects chosen, we may mention the Cepheids, the corona, solar radiation, Saturn's rings, celestial 'wanderers', the evolution and expansion of the universe, novæ, interstellar gas, in order to show the range covered by the book.

The treatment is simple and popular, astronomers of many countries are fairly represented in the appropriate sections and the book will be read with very considerable interest, even where the reader does not agree with the author's point of view.

Worlds in the Making

By R. Barnard Way. Pp. 136. (London: The Chatterbox Co., Ltd., 1934.) 3*s.* 6*d.* net.

THE evolution of planets from primordial matter through nebulæ, galaxies and stars is here described in simple language, accompanied by a general description of the universe as it is at present and of the various objects composing it, from electrons to spiral nebulæ. The development of our own earth up to its present physical state and into a possible future one is given in detail, forming the main theme of the second half of the book, which is well illustrated with numerous drawings and diagrams made by the author. Although obviously intended for young people, the presentation of the subject is not too childish to appeal to older readers who require a brief elementary survey of the origin of worlds in general and of our own in particular.

Intermediate Physics

By Dr. C. J. Smith. Second edition. Pp. xii+900. (London: Edward Arnold and Co., 1935.) 16*s.* net.

THE call for a second edition shows that Dr. Smith's book is well appreciated, and it is clear that a great amount of work has been done in its preparation. Amongst the additions and improvements may be noted the theory of dimensions in Part I, a remodelling of a great deal of Part II, an increase in the matter dealing with interference in Part III, a short section on supersonics in Part IV, and an entire rearrangement of Part V. Candidates in university scholarship examinations should now find all the material for answering the papers in physics, and the harder matter is carefully distinguished from that dealing with fundamentals, which latter is adequate for the needs of the intermediate or pass candidate, to whom the book can be highly recommended.

Phosphate in the Western Basin of the North Atlantic*

By H. R. Seiwell, Woods Hole Oceanographic Institution

SINCE various investigators have illustrated the dependence of marine plant growth on certain inorganic substances in the sea[1], a knowledge of the variation and mechanism of the phosphate distribution is significant in questions of marine fertility. Dissolved phosphate investigations have taken a place along with studies of other fundamental properties of sea-water, and lately these results are also being used as identifying properties for the purpose of tracing the origin and courses of water masses in the sea.

Phosphate observations considered here were obtained during the *Atlantis* cruises of 1931 to 1933 in the western basin of the North Atlantic[2]. The investigation of dissolved phosphate in this region is similar to that made in the South Atlantic within recent years by the *Discovery*[3] and the *Meteor*[4]; and in the northern North Atlantic by the *Meteor*[5].

In general, within the area of investigation, vertical distribution of phosphate in the upper part of the water column parallels temperature (and density) distribution; the homogeneous water overlying the principal thermocline being almost exhausted of phosphate. Principal differences in vertical distribution of phosphate are indicated by variation in thickness of the phosphate-poor surface layer, and the variation of depth and value of the maximum phosphate concentration. The maximum horizontal variation of phosphate occurs at mid-depths.

It is convenient to classify the vertical distribution of phosphate phosphorus into three types characterising different parts of the western North Atlantic basin.

1. Convergence type: characterises the region influenced by the principal American coastwise convergence[6] (extending from Florida to Nova Scotia). The phosphate-poor surface layer (0–5 mgm. P per m.^{3}) is not more than 100 metres thick; below this, phosphate increases to a maximum value of about 30 or more mgm. of P per cubic metre at depths of 300–500 metres and then decreases slightly in still deeper water; at 2,000 metres, phosphate content is usually just less than 30 mgm. P per cubic metre.

2. Central Atlantic type: characterises the northern half of the area, east of the American coastwise convergences. The phosphate-poor surface layer (0–5 mgm. P per m.^{3}) overlies the principal thermocline and is generally 300–400 metres thick; below this, phosphate content increases to a maximum value of about 30 (or more) mgm. P per cubic metre at depths of 800–1,000 metres, and then decreases slightly in still deeper water.

3. Tropical Atlantic type: characterises the southern part of the area; the phosphate-poor surface layer (0–5 mgm. P per m.^{3}) is about 100 metres, or less, in thickness, below which phosphate rapidly increases to a well-developed maximum value of 50–60 mgm. per cubic metre at intermediate depths of 600–800 metres, and then decreases in still deeper water; at 2,000 metres, phosphate content is generally in the vicinity of 30 mgm. P per cubic metre.

The vertical distribution of phosphate (Fig. 1) shows that the water column becomes progressively richer in its most stable part (the thermocline), so that considerable resistance is offered to enrichment of the surface layers of the open ocean by the usual agencies which bring about vertical circulation (winter chilling, wind stirring, etc.). It is this condition which has led us hitherto to assume that well-developed discontinuity layers, such as occur in the tropical Atlantic, effectively shut off a supply of phosphate from the rich midstrata to the illuminated surface layers[7].

The phenomenon of turbulence which accompanies all movements of sea water may be a significant factor in transporting phosphate, and other dissolved nutrient substances, from the rich midstrata, up into the illuminated surface layers of the open ocean. Turbulence results from impulses given to the water mass; in the case of a horizontal current, there is an accompanying vertical displacement of water particles which brings about an exchange of properties between different strata. The magnitude of turbulence, or eddy motion, in the sea is expressed by the coefficient of eddy conductivity (having the dimensions of grams per centimetre per second) which appears to lie usually between 1 and 20 C.G.S. units[8].

To make use of the concept of turbulence for the purpose of calculating the amount of phosphate transported vertically from the depth of its maximum concentration up into the illuminated layer of the sea, the phosphate gradient and the average eddy coefficient characterising that part of the

* Contribution No. 77 from the Woods Hole Oceanographic Institution.

water column involved in the transport must be known. The magnitude of the transfer of phosphate by eddy conductivity may be calculated by the following equation:

$$N = \frac{A}{\rho}\frac{dP}{dz},$$

where N represents phosphate (grams) transported per second through a square centimetre of area; A, the coefficient of eddy conductivity (C.G.S. units); ρ, the density of the water; and dP/dz the average vertical variation of phosphate (grams per cubic centimetre per centimetre). The phosphate gradient can be measured with a fair degree of accuracy, but the average eddy coefficient must be approximated at the present time. The method and arguments used to determine the order of magnitude of eddy conductivity in the western North Atlantic have been previously discussed by me[2], and here it will suffice to state that in that part of the water column involved in the upward transport of phosphate (between depth of phosphate maxima and homogeneous layer) the average eddy coefficient was calculated to range from about 30 C.G.S. units, north of lat. 30° N., to 10 C.G.S. units or less, south of lat. 15° N.

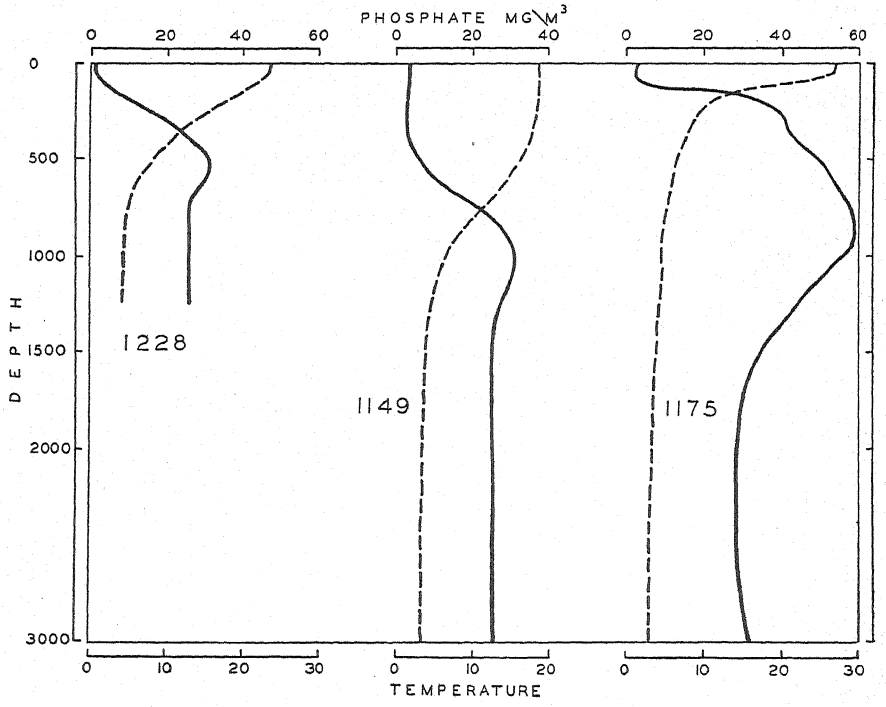

FIG. 1. Vertical distribution of phosphate (mgm. P per m.³) and temperature at *Atlantis* stations 1228 (35° 57′ N., 73° 05′ W.), 1149 (32° 59′ N., 60° 16′ W.) and 1175 (6° 50′ N., 40° 25′ W.); February-April 1932.

The amount of phosphate transported annually from the phosphate-rich midstrata to the homogeneous water overlying the thermocline, as calculated, ranged from $3{\cdot}0 \times 10^{-4}$ gm. P per square centimetre of horizontal area in the extreme south to more than 6×10^{-4} gm. in the north central part of the area. Thus, in the southern half of the area the higher midstrata concentrations of phosphate (with correspondingly greater variations with depth, Fig. 1) are offset in their influence on the eddy transport of phosphate by decreased turbulence.

After phosphate has been transported into the water overlying the principal thermocline, it is available for phytoplanktonic consumption either by direct utilisation (if the thermocline is sufficiently close to the surface) or by stirring of the relatively homogeneous layer by winds, waves, etc. If this transported phosphate enriches the water over the thermocline uniformly, the increased concentration per unit volume may be calculated by dividing the amount of phosphate transported per unit area[8] by the thickness of the homogeneous layer.

According to our calculations, the annual phosphate enrichment of the homogeneous water, per cubic metre, decreases in a south–north direction from more than 60 mgm. P in the south to less than 20 mgm. in the north central part of the area. Hence, in the south a unit volume of homogeneous water receives about four times as much phosphate by eddy transfer as it does in the north, whereas in the south the total supply, per unit of surface area, to the water over the thermocline is only about one half as much as in the north. The discrepancy results from the lesser thickness of the water layer overlying the thermocline in the tropics; and the contrast indicates that, within the area, regional variations of chemical fertility cannot be estimated on the basis of unit volume measurements alone. Indeed, this analysis also suggests that, when comparing the fertility of other regions, a consideration only of the concentrations of nutrient substances per unit volume of water may lead to erroneous interpretation of conditions, particularly if the regions differ

in vertical distribution of their physical and chemical qualities.

On the basis of our recent results, it is tentatively concluded that, throughout the entire basin of the western North Atlantic, regardless of existing vertical density gradients, there is a significant eddy transfer of phosphate from the rich midstrata to the impoverished surface layers. This, in general, is opposed to previous ideas that, in the open ocean, well-developed discontinuity layers restrict vertical transfers of dissolved nutrient substances from the rich underlying midstrata.

It is apparent that, in the open ocean, the consequence of the eddy transfer of nutrient substances to biological fertility will depend on the extent to which plant activity is confined above the principal thermocline; for, if photosynthetic activity should, for example, occur within the illuminated part of the thermocline of tropical waters, then there would be available for plant growth a supply of nutrient substances as great as occurs anywhere in the oceans. However, the vertical distribution of oxygen and phosphate in this region[2] suggest that, in general, the depth of plant activity is limited principally to the water overlying the thermocline, even in low latitudes where the latter extends well up into the illuminated part of the water column. This idea is, at least, not refuted by the few results of phytoplanktonic investigations in mid Atlantic.

That some factor other than light may limit the depth of photosynthesis seems probable; hydrographic conditions in the western North Atlantic suggest that temperature may bar access to tropical latitudes for plant species adjusted to low temperatures, and thus restrict phytoplankton to the warmer water over the thermocline. In mid latitudes the great thickness of the overlying warm water (Fig. 1) would, for lack of light, prevent a continuous phytoplanktonic distribution between surface strata in high latitudes and subsurface illuminated strata of similar temperature in the tropics. Phytoplanktonic communities in the tropics would thus tend to be limited to 'high temperature' species; and the lower and cooler parts of the photic layer would be left barren of plants unless some development of 'low temperature' organisms had taken place there independent of any direct connexion with similar 'low temperature' communities in high latitudes to the north or south.

Scientific Research in China

The Academia Sinica

By V. K. Ting, Secretary-General, Academia Sinica, Nanking, China

'ACADEMIA SINICA' is the official designation for the Central Research Organisation established by the National Government in Nanking in 1928. According to its charter, it is the highest institution for scientific research in China. In the mind of its founders it is to be a sort of Academy of Sciences, Department of Scientific and Industrial Research, and Kaiser-Wilhelm-Gesellschaft combined. Unlike all the other institutions, it is independent of political control, for it does not come under any Ministry or Board, but is directly responsible to the National Government, which means the President of the Republic. It also functions as the highest national organisation for conferring honours upon individuals and institutions both at home and abroad that have distinguished themselves in science. For the purpose of directing and co-ordinating scientific activities in China, there is a council consisting of thirty members, selected from among the scientific workers of the country, and a certain number of ex-officio members who have also the right to elect candidates for the presidency of the Academia Sinica.

So far, however, its work as a group of closely connected and co-ordinated institutes for the purpose of carrying out original research has been more important than its other functions. As it

is constituted at present, it controls ten research institutes, including physics, chemistry, engineering, astronomy, meteorology, zoology and botany, psychology, geology, history and philology (including anthropology and archæology), and the social sciences. Thus the scope of research is extremely wide; for, on one hand, it includes such routine service as meteorology; on the other, it embraces the social sciences as well as history and philology, which are usually considered to belong to the 'humanities'. The following brief account will give some idea of the work being done in these institutions.

Observatory Hill because an observatory was built there in the year 1341, and continued to exist down to the beginning of the seventeenth century. The present Institute possesses up-to-date equipment, and maintains in addition a seismological station. It has a radio-transmitting station of its own, and broadcasts its forecasts daily. It keeps in close touch with the provincial meteorological stations all over China, and maintains several branch stations of its own, including one at Kokonor and another at Lhasa. For the purpose of upper air investigation, weekly flights are made by arrangement with the Bureau of Aviation.

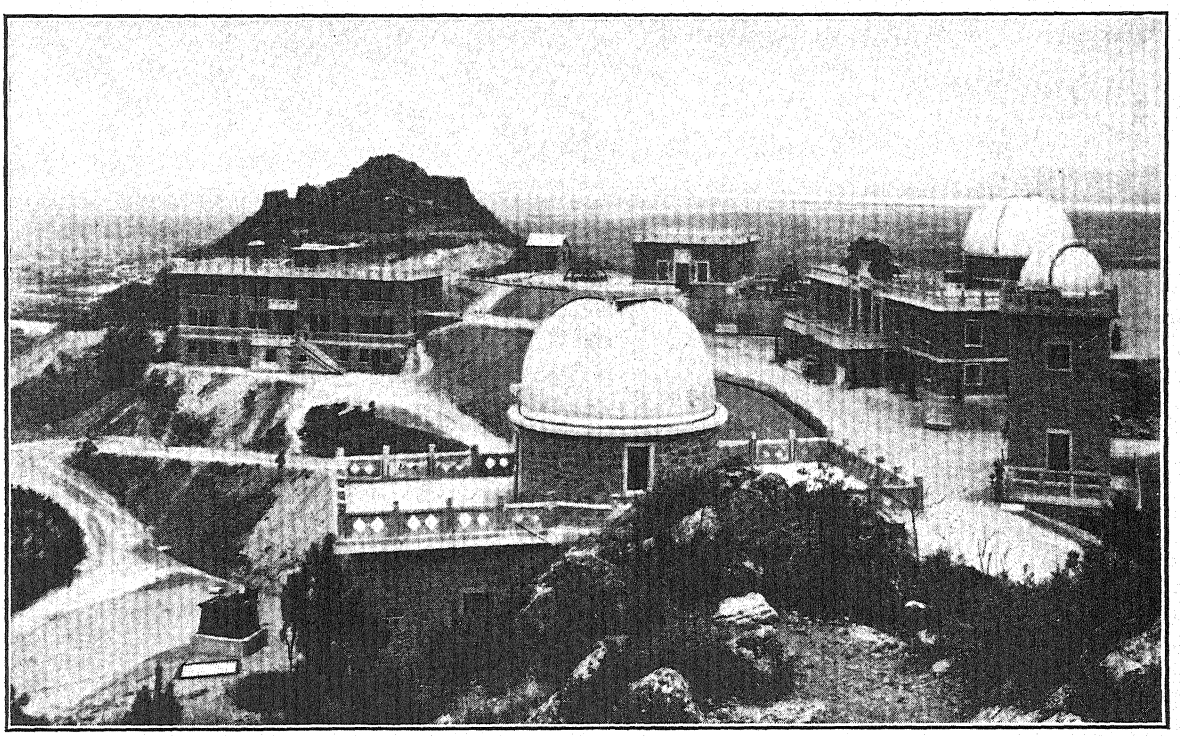

FIG. 1. Astronomical observatory of the Academia Sinica, on the Purple Mountain, near Nanking.

The Institutes of Astronomy and Meteorology are both located in Nanking. The former is built on one of the peaks of the Purple Mountain, 900 ft. above the plain just outside the east gate of Nanking (Fig. 1). It is one of the best equipped observatories in the Far East, having at its disposal one 600 mm. reflector, one 135 mm. meridian circle and one 200 mm. equatorial refractor with a 150 mm. astro-camera. In addition to compiling the almanac, supplying time service and determining geographical co-ordinates, the Institute of Astronomy carries out regular photometric and spectrophotometric studies of the sun, the planets and stars, makes observations of the variable stars, and studies solar activity with a Hale spectrohelioscope. The Institute of Meteorology is situated on another hill in the city. It is called

Three more institutes are located in Nanking: namely, those of geology, zoology and botany, and history and philology. The Institute of Geology has four sections: namely, stratigraphy and palæontology, petrology and mineralogy, economic and dynamic geology, and geophysics. Thus in scope it does not differ much from the National Geological Survey of China, which is an older institution under the Ministry of Industry, but more attention is paid to the theoretical side of geology. In co-operation with the National Geological Survey, it has also done considerable mapping, especially in the Yangtze Valley. Its publications, although less voluminous than those of the National Survey, have also gained international recognition. Its director, Dr. J. S. Lee, at the invitation of the Universities' China

Committee in London, has recently lectured on the geology of China before the Geological Society of London and in various universities of Great Britain.

The Institute of Zoology and Botany was originally the Metropolitan Museum of Natural History, which devoted itself exclusively to faunal and floral studies, especially of south and south-west China. With the organisation of a comprehensive National Museum under the joint auspices of the Academia Sinica and the Ministry of Education in 1934, it has been reorganised into the present Institute in order to avoid unnecessary duplication. At present the Institute concentrates its efforts on marine biology, especially fisheries, economic entomology and plant pathology.

Of all the institutes, that of history and philology is the best known outside China because of the important discoveries at Anyang in north Honan province, made by the Section of Archæology. For the first time, ancient Chinese history is being checked by carefully planned and executed excavations. The site was the capital of the Shang Dynasty (1500–1200 B.C.), and had been known since 1899, when bones inscribed with archaic characters were first brought to the antiquarian market. Since 1928, excavation work has been going on without interruption. An enormous number of inscribed bones and shells, bronze, pottery, stone implements and stone carvings belonging to different cultural periods have been uncovered, and buried palaces and mausoleums have been carefully unearthed and mapped. Some of the treasures are to be shown at the coming Exhibition of Chinese Art in London. International recognition came in the form of the award of the *prix de Stanilas Julien* by the French Academy. No less important although less spectacular are the works of the historical and the linguistic sections, both of which have issued a number of publications.

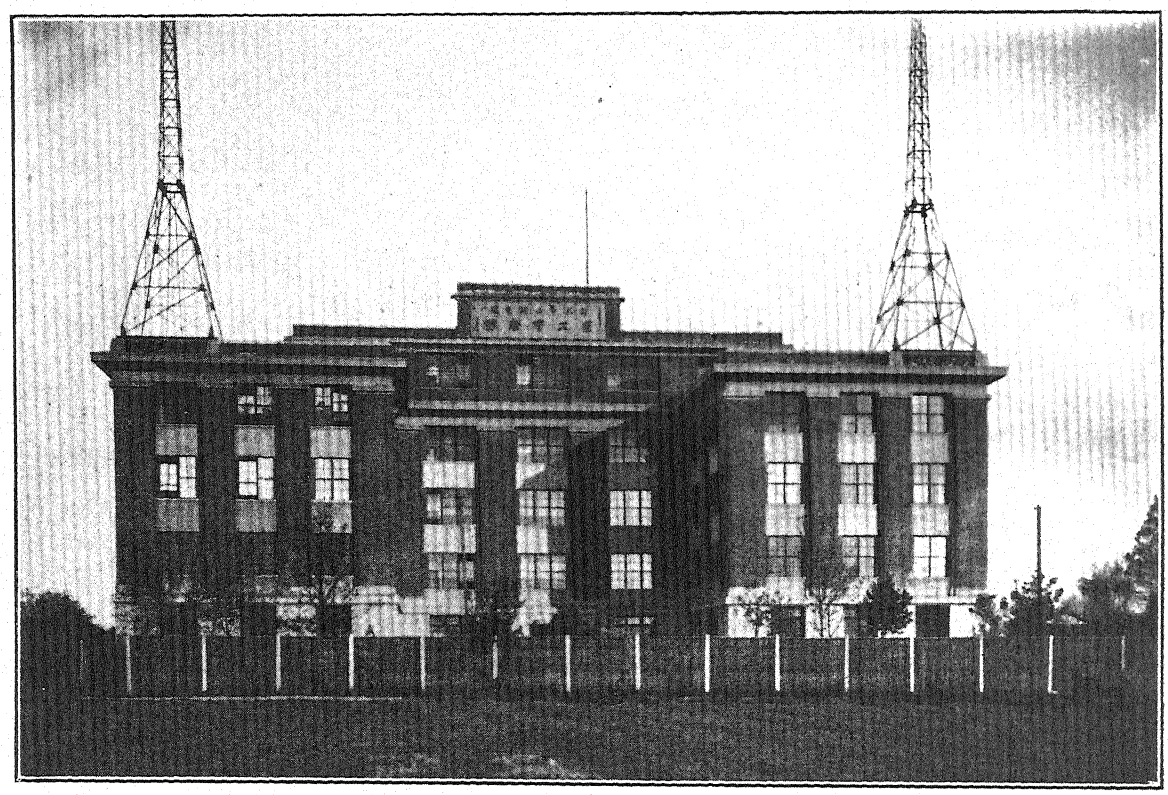

FIG. 2. Laboratory for Physical Sciences and Technology, Shanghai, housing the Institutes of Physics, Chemistry and Engineering of the Academia Sinica.

The Institute of Social Sciences was also founded in Nanking. It had four sections: those of law, economics, sociology and ethnology, the last of which has been the most productive. A number of monographic studies have been made on the primitive tribes in north-east and south-west China. In 1934 it was amalgamated with the Institute of Social Survey of the China Foundation for the Advancement of Education and Culture, and its head-quarters moved to Peiping. Thus reorganised, the new Institute devotes itself entirely to economic studies, and the old section of ethnology has been changed into that of anthropology and put under the Institute of History and Philology.

The Institutes of Psychology, Physics, Chemistry

and Engineering are located in Shanghai. That of psychology is the smallest, and at present its work is largely confined to neural physiology and anatomy. It is being moved to Nanking. The three other institutes are, however, in their permanent quarters, which form a two-story building with a total floor space of 75,000 sq. ft. built in 1933 at the cost of £50,000 (Fig. 2). Both physics and chemistry possess excellently equipped laboratories. In addition to pure research, efforts are being made to study local problems. Thus, in chemistry, work has been done on Chinese drugs, paper and glass-making, metallurgy of certain rarer minerals; in physics on wireless, X-rays and geophysical surveying; and in engineering on ferrous metallurgy and ceramics, the aim being the better utilisation of China's resources in industrialisation. Both the Engineering and the Physical Institutes maintain standards testing laboratories; the latter fulfils partly the function of a bureau of standards.

The Academia Sinica as a whole receives from the National Treasury a grant of £100,000. Together with the income from its reserve fund and other grants, its budget during the last few years has averaged about £150,000.

Obituary

Prof. Edwin B. Frost

EDWIN BRANT FROST, who died on May 14, was born on July 18, 1866, at Brattlebro, Vermont. His father, Carlton Pennington Frost, was the seventh in descent from ancestors who had left Ipswich, Suffolk, in 1634 in order "to avoid the more savage oppression of England". They were shipwrecked off Yarmouth, but the family started again in 1635, and after a voyage of fifty-three days they reached Boston, and settled in New Hampshire, Vermont and Maine. Edwin Brant Frost derived his second name from the wife of his paternal grandfather Benjamin, who had married Mary Catherine Brant. His early home was in the green hills of the valley of the Connecticut River. His father was surgeon-major for some months in the Civil War and for three years after it, and in 1871 he was called to a professorial chair in medicine at Dartmouth College, Hanover, New Hampshire. Thus it came about that his two sons spent their learning years at Dartmouth College.

Edwin B. Frost, the younger son, graduated as A.B. in 1886, in physics. In the following year he accepted an invitation from Prof. C. A. Young to go to Princeton. Young was then engaged in writing his textbook on general astronomy, and Frost gave help in reading the proofs—an admirable way of taking a course in astronomy. He became A.M. in 1889, and then came to Europe to continue graduate studies, first at Strassburg under Kohlrausch, and later at the Astrophysical Observatory, Potsdam, under Prof. H. C. Vogel.

At Vogel's suggestion, Frost made observations with a thermopile to study the distribution of radiation over the sun's disc for comparison with Vogel's earlier study of ultra-violet radiation. Nova Aurigæ was discovered by Anderson in February 1892, and during Dr. Scheiner's temporary illness Frost photographed the spectrum of the nova with a small improvised spectrograph attached to the Repsold astrographic refractor. He also took a share with Scheiner in the measurement and reductions of the photographs of the cluster in Hercules, taken with the same refractor.

On his return from Europe in the autumn of 1892, Frost took up work as instructor in physics at Dartmouth College, Hanover, and devoted spare time to the translation of Scheiner's textbook "Die Spectralanalyse der Gestirne" (1890). This translation with extensions was published with Messrs. Ginn and Co., in 1894, under the title "Astronomical Spectroscopy".

His participation in the research activities at Potsdam, however, had made Frost aware of possibilities remote from pedagogy. He became professor at Dartmouth College in 1896, and two years later he was appointed to the chair of astrophysics in the University of Chicago. In 1898 he joined the staff of the Yerkes Observatory at Williams Bay under the directorship of Dr. G. E. Hale, and he had among his fellow workers Barnard and Burnham and Dr. W. S. Adams. When Dr. Hale was searching (1903–4) for a site for solar observations for the Carnegie Institution, Frost was called on to undertake the duties of deputy director. In 1904 Dr. Hale resigned the directorship of the Yerkes Observatory, and Frost succeeded him as director in 1905.

Hale had designed and constructed the Rumford spectroheliograph, which was mounted on the Yerkes telescope. To Frost had been assigned in particular the duty of designing and using the Bruce spectrograph (1902), to replace the earlier spectrograph used by Hale and Ellerman, on the 40-inch refractor in their study of the spectra of stars of the Fourth Type. The general design of the instrument was prepared by Frost and Dr. Hale, and it was carried out under the superintendence of Mr. Ritchey in the workshops of the observatory. With this instrument, Frost and Dr. Adams secured their observations of the radial velocities of twenty stars of the Orion type (helium stars). Thus whilst Dr. Campbell at the Lick Observatory was attacking with splendid success the task of measuring the radial velocities of stars with well-defined lines in their spectra, Frost devoted his attention to stars of class *A* with less-defined lines,

and showed that such stars could be dealt with successfully. Hence it came about that velocity determinations have been accumulated for more than 500 stars, by the joint work of thirty-five observers, including Frost, Mr. Barrett, Mr. O. J. Lee and Dr. Otto Struve, who had joined the staff in 1922. Out of more than 4,000 photographs, Frost had taken about 9 per cent, Mr. Barrett about 37 per cent, Mr. Lee about 11 per cent, Dr. Struve nearly 23 per cent. Out of the 500 stars observed, 187 or 37 per cent were believed to be spectroscopic binary stars by reason of their observed variable velocities.

Besides editing in 1907 the solar observations of Dr. C. H. F. Peters made at Hamilton College, Clinton, N.Y. in 1860–70—a task involving labour out of all proportion, it must be confessed, to the scientific value or availability of the results—Frost published more than a hundred papers, mainly in the *Astrophysical Journal*, of which he was then active managing editor for twenty-seven years. Seven volumes of *Publications of the Yerkes Observatory* have appeared recording the work of many workers in diverse lines of astronomical activity. No wonder that with so much editorial work in the daytime, his eyesight suffered when he imposed on it also the strain of observational work at night. It was on December 15, 1915, that detachment of the retina declared itself, and with cheerful belittlement of his affliction, he used to estimate the gradual diminution of the percentage of normal vision left to him as years went by. He resigned the directorship of the Yerkes Observatory in July 1932.

Frost will be remembered with respect and affection by his many students and colleagues as a man of peculiarly genial nature in human relations, of very varied interests—natural history, botany, music, literature—and for his amazing courage and cheerfulness in carrying on his life's work in spite of the affliction of increasingly defective eyesight. A large circle of friends will join in deep sympathy with Mrs. Frost and her family, and in good wishes for the success of Dr. O. Struve in carrying on the directorship of the Yerkes Observatory.

News and Views

Past and Future of Chemical Industry

In his medallist's address to the Society of Chemical Industry at Glasgow on July 3, Dr. E. F. Armstrong briefly reviewed developments in chemical industry in the last twenty-five years, with particular reference to his own experiences with Crosfield's and Gossage's. Noting the unpreparedness of chemical industry for the Great War, although chemists and chemical industry came well out of that searching ordeal, he urged the importance of maintaining in peace time in active being those industries which in war will furnish the plants, the materials and the chemists necessary for war production. Another war might make even greater demands on our chemical resources, and modern mass-production plants cannot be improvised. Apart from the ability of the industry to expand rapidly to supply war needs, the availability of the technical personnel capable of handling intricate manufacturing processes as well as emergency problems is even more important. Dr. Armstrong directed attention to the tendency towards continuous processes, automatically controlled, and viewed with anxiety the future position of important products still made in Great Britain by batch processes. He referred to the systematic work required to secure the best results when a particular aggregation of plant has to be adapted to making several substances in turn, as in the colour industry, and briefly discussed the rationalisation of chemical industry as well as the formation and work of the Association of British Chemical Manufacturers and the effect of tariff changes on chemical industry.

Looking to the future, Dr. Armstrong advocated changes in the management of the Society of Chemical Industry, including a recognition of the ephemeral character of most of the meetings, papers and discussions, and a much stronger participation in public affairs by the chemist. The training of the chemist in industry is not finally complete without some study of management, and it is essential for the chemist to realise that management can be scientific, and although nothing can substitute personality a thorough knowledge of a subject is equivalent to power. Labour questions offer an important field for experiment in which chemical industry has already pointed the way, and a reduction in working hours, a later entry into industrial life as well as an earlier departure are all matters obviously desirable from technical as well as social and economic points of view. Dr. Armstrong made a powerful plea for more attention to the problems of the smaller firms, which could frequently be solved by closer co-operation particularly in development. It is probable that, in the future, allied industries will tend to become more and more chemical manufacturers, and the importance of the chemist thus to increase. Technical men must prepare themselves to meet the situation; there is a suspicion that the individual chemist has not progressed individually with his industry. It is essential to attract the best type of young men and to see to it that they are encouraged and adequately rewarded from the start.

Ecological Expeditions in East and West Africa

The Department of Botany at the British Museum (Natural History) has received 838 plants collected on the Cambridge Botanical Expedition to Nigeria by Messrs. P. W. Richards and R. Ross. The main object of the expedition was to make an ecological

survey of a limited area of West African rain-forest comparable with those previously made by Mr. Richards in Guiana and Sarawak. This meant a study of the floristic composition and structure of various types of primary forest on one hand, and a study of soil and micro-climatic conditions on the other. In addition, Mr. W. J. Fletcher Cambell made a general soil survey. Mr. Ross studied the succession of secondary forest on old farms and Mr. G. C. Evans worked on the growth, transpiration and assimilation of two species of undergrowth shrubs. The base camp was about five miles from Akilla in the Shasha Forest Reserve, Ijebu Province, and the area worked was mostly within a radius of five miles from the camp. Four months were spent here, and a visit, via the creeks, was made for a fortnight to Nikrowa in the Okomu Forest Reserve, Benin Province, where the rain-forest is said to be the finest in Nigeria. Collecting was mainly incidental to ecological work. The specimens are particularly rich in forest trees, and special attention was paid to Bryophytes. It was possible to fix a hygro-thermograph in a tree top eighty feet from the ground in primary forest and to take daily readings over a period of several weeks. A mud and bamboo laboratory was built with a dark room quite efficient for working with panchromatic plates.

THE collection of plants made by Mr. P. M. Synge on the British Museum Expedition to Uganda and Kenya has been received; it contains 1,231 numbers. Mr. Synge's main object was the study of vegetational zones in the higher parts of the East African mountains and the environmental factors influencing them. Particular attention was paid to the arborescent Senecios, and a long series was collected. Some observations were made on humidity and temperature in the higher zones, but a complete record could not be obtained. Dr. Taylor made the main collections on the joint visits to the Aberdare Mts. and Birunga Mts. Three visits were made to Mt. Elgon and one to Mt. Kenya, while the Nyamgasani valley on the south side of Ruwenzori was ascended and collections made up to the limit of vegetation. Some water plants and algæ were collected from the Nyamgasani lakes: a little collecting was also done in the papyrus swamp around Lake Kioga.

Archæological Exploration in Africa

PROF. LEO FROBENIUS, president of the Frankfurt Research Institute for Cultural Morphology, who has recently returned from his twelfth expedition to Africa, claims, it is said, that the results of his explorations in the Libyan Desert and the Sudan have now established the validity of his theories of the origin and direction of diffusion of the periods, or phases, which he distinguishes in the history of civilisation. It will be remembered that Prof. Frobenius, working on the material which he has been engaged in collecting in Africa for nearly thirty years, has not only produced an elaborate classification and scheme of distribution of the main forms of culture in that continent, but has also put forward certain views as to their historical development and affiliations. In an interview with the correspondent of *The Times*, which appears in the issue of July 31, Prof. Frobenius is reported as saying that he has now discovered in the Neolithic of the Sudan, the period in which agriculture and the domestication of animals first appear, the missing, but essential, link in the chain of evidence joining prehistoric to historic cultures. It is further reported that, since October last, a staff of twenty research workers attached to the Institute and distributed from Scandinavia to Southern Rhodesia, including France, Spain, Italy, North Africa, Abyssinia and Arabia, has been engaged in filling in gaps in the evidence and adding details to the chart of cultural distributions, which is now approaching completion.

FURTHER particulars are now to hand of an archæological discovery in Tanganyika reported early in July. According to a dispatch from Nairobi in *The Times* of August 1, Commander Nino del Grande, leader of an expedition collecting snake poison for the preparation of a snake-bite serum, camped for five days on the site of the ancient city discovered near Nguruka. He reports that the city is four and a half miles long by one and a half miles broad and is constructed terrace-wise on the wall of the Great Rift escarpment. Remains of houses, estimated to number four thousand, were found. Each had three or four rooms and stone walls four feet in thickness. Large stone tombs, one containing a skeleton, were found in the valley below. It is given as the opinion of Commander del Grande that no very high antiquity is to be assigned to these remains. It is thought that they may be about five hundred years old and the work of an advanced tribe, possibly the ancestors of the Wambulu now living some fifty miles away. The site is being examined by Dr. L. S. B. Leakey, whose verdict on the relation of these remains to other vestiges of stone structures found in various parts of East Africa should be of signal importance for the cultural history of the southern half of the continent.

Excavations in the Fens

THE importance of intensive exploration of the Fens, which led to the formation of the Fenland Research Committee at Cambridge, under the presidency of Prof. A. C. Seward, has already been referred to in these columns. Some of the results already obtained are now on exhibition at the British Museum, Bloomsbury, at the head of the main staircase. The sites selected are mostly between March and Mildenhall, and more or less connected with the Ouse, Cam and Bedford Rivers, where the post-glacial period is represented by peat, clay and silt, in which a sequence of human occupations can be traced, while light is further thrown on land movement and forest development. Waterways and promising sites have been traced by surveying on the ground and from the air, and an interesting feature is the occupation in Roman times of what used to be river banks but are now parallel mounds flanking slight depressions, in which shrunken rivers originally flowed. The contraction of the peat

has left these banks in relief, and the amount of this wastage is indicated by the Holme post, which proves that Whittlesea Mere is about 11 ft. lower than in 1848. The co-operation of workers in many fields has been secured, and much attention given to the botany, geology and zoology of the region, which is linked to North Germany and Scandinavia by its foraminifera and tree-pollen, to say nothing of changes in relation to sea-level. The work supervised by Dr. Grahame Clark in association with Mr. C. W. Phillips and Major Fowler has been rendered more difficult by the presence of water in the deeper cuttings; but funds have been provided, mainly by the Percy Sladen Memorial Fund, and the present exhibition, which will be open at least two months, will reveal to a larger public the potentialities of the Fens as a field of research in various branches of science.

Iron Age Site on the Sussex Weald

A FURTHER addition to the sites of industrial activity in Sussex in later prehistoric and Roman times, for which archæologists are indebted to the activity in investigation of Mr. S. E. Winbolt, is made by the discovery of an Early Iron Age camp on the Weald in Piper's Copse, one and a quarter miles east of North Chapel, West Sussex. The situation is remote and the discovery was due to the fact that a fox had dug its earth in a dry place where a small iron smelting hearth had been constructed in the inner slope of a bank. This was found on investigation to be the north-west end of an enclosure formed by a bold bank and deepish ditch, in good condition, except on the south-east, where an attempt had been made at levelling. The dimensions of the camp, Mr. Winbolt states in a communication to *The Times* of August 5, are a little more than 300 ft. by 270 ft. outside measurement, the inner area comprising about 1¼ acres. The height of the rampart, where best preserved, is 14 ft. from the bottom of the ditch. Two points of special interest arise in connexion with this discovery. The camp lies on the Wealden level (*c.* 120 ft.) and although Early Iron Age camps are known on heights fringing the Weald, such as at Holmbury and Hascomb, Saxonbury and Dry Hill, this is the first to be recorded at the Wealden level. The second point of interest is its date and purpose. These are fixed by red burnt material, charcoal, nodules of local iron ore and five fragments of La Tène iii pottery, as well as by many big lumps of iron ore lying near by. The site lies about two miles from the eastern slope of Blackdown near a stream flowing into the Arun and is in the middle of a country rich in iron ore of a moderate quality, where iron furnaces and forges of late medieval date abound, as, for example, at Mitchell Park, Shillinglee, Ebernoe and Roundwyck. Mr. Winbolt points to this as a further instance of the previous existence of Iron Age and Roman iron workings where medieval and Tudor workers are found.

Science and Culture: A new Indian Monthly

IT was anticipated by the founders of the Indian Science Congress that the Congress would stimulate in India an interest in science and in scientific research. At the time of its formation, the reforms in Indian university education resulting from the recommendations of the Curzon Commission were becoming effective and the universities were beginning to be centres of research. The spirit of scientific inquiry grew during the War period, and if the formation of scientific societies and the issue of scientific journals are to be regarded as criteria of increased interest in science, the hopes of the founders of the Congress have been fulfilled. There are in existence a number of specialist societies, the most recent addition being a Physical Society, and we referred recently (**135**, 410, 441; March 16, 1935) to the foundation of the National Institute of Sciences of India with its affiliated academies, the Asiatic Society of Bengal, the U.P. Academy of Sciences (Allahabad), and the Indian Academy of Science (Bangalore). In so large a country as India it is natural that there should be more than one academy, but the choice of names for these bodies is not happy and is likely to cause confusion in references to their publications.

THE more general aspects of science have in the past been dealt with by the weekly periodical *Current Science*, and we have now received the first issue of a monthly journal, *Science and Culture*, published by a non-profit corporation in Calcutta. The object of this periodical "is the dissemination of scientific knowledge amongst the public and advocacy of its application to all walks of life as far as practicable". The first issue contains a number of valuable articles the majority of which deal with topics of local interest, but the lecture by Prof. M. N. Saha "Ultimate Constituents of Matter" will attract a wider public. There are, in addition, reviews of books and a correspondence column. The latter, containing preliminary accounts of scientific investigations, seems scarcely in keeping with the other contents. These 'letters to the editor' would have appeared more suitably in *Current Science*. We welcome this new periodical, and if the high standard of the first number be maintained its success is assured.

British Empire Naturalists' Association in Jersey

IN the official report of the summer meeting of the British Empire Naturalists' Association in Jersey, Mr. Leslie Beckett, honorary organising secretary of the Association, states that many rare plants and birds were observed. Particularly was the island fruitful in flora, and of the more interesting examples noted, mention is made of many plants rare or unknown in England but quite well established and safe in Jersey; for Jersey is the northern limit of many Continental and North African plants. The English or five-spotted catchfly (*Silene gallica*) was found in profusion nearly everywhere, and near Crabbe, the party found the rare variety, *quinquevulnera*, which few of the botanists present had seen before. One party found a big patch of the Jersey bugloss (*Echium plantagineum*) between St. Brelades and Corbière. On the sand-dunes near Le Pont was found the rare yellow broomrape (*Orobanche ritro*) which is not found elsewhere between this

locality and Spain. On the last afternoon of the fortnight, *Convoluta Roscoffensis* was noted, an extraordinary example of symbiosis between a worm and an alga. Of bird-life, Mr. Le Maître led a party to the cliffs at Crabbe, to photograph the herring-gullery there, and the Rev. Pere Burdos led a party to the Pinnacle, a rock 200 ft. above sea-level near Plemont, where the peregrine falcon, raven, puffin and nesting guillemots, razorbills and oyster-catchers were seen. The granites in which Jersey is so rich interested the geologists, and while studying a quarry near Gorey Castle the rare hyssop-leaved loosestrife plant was noted. The first meeting of the London branch of the B.E.N.A. will be held at the Furnival Hall, Furnival Street, on October 16, when Mr. J. Ramsbottom will lecture on "Moulds and Mushrooms".

Technical College Buildings

IT is little less than astonishing that a country like Great Britain, which has been the pioneer in scientific work and retained so high a standard of scientific achievement, should have such a paucity of literature dealing with material needs in the matter of buildings and equipment necessary for its field of activity. Books dealing with laboratories can be counted on the fingers, while for any wide general account of technical institutions dealing with the application of science to the trades, it is necessary to go back nearly half a century. The report, published at the expense of the Carnegie United Kingdom Trust, by a Joint Committee of the Association of Technical Institutions, the Association of Principals of Technical Institutions with representatives of the Royal Institute of British Architects and the Institute of Builders and a member of the staff of the Board of Education is therefore to be specially welcomed, particularly at the present time when the demands for buildings for technical education are so marked (London : Association of Technical Institutions and the Association of Principals of Technical Institutions, 1935. 3*s*.) The volume, consisting of some 150 quarto pages including plans and illustrations, is the work of a representative committee the personnel of which is sufficient evidence of authority. The opening two chapters deal with general requirements including service supplies and accommodation, and these are followed by concise articles on the special needs of specific subjects, some twenty in all, embracing such fields as leather industries, printing and textiles in addition to the more generally taught trade principles. These chapters, which occupy the bulk of the volume, have been compiled by panels of experts intimately associated with the required tuition. The brochure concludes with two chapters illustrated with plans and photographs of recent British and Continental examples of buildings, and should be of great value to all concerned with the development and execution of schemes for technical education.

Temperament in Industry

THE effects of having the wrong type of persons in positions of authority were discussed by Dr. May Smith, senior investigator to the Industrial Health Research Board, in a lecture on May 27 forming part of a course on the temperamental factor in industry arranged by the National Institute of Industrial Psychology. She said that it was not uncommon to find that a high rate of sickness absences was the result of having a supervisor with the wrong temperament for his job. Sickness is also frequently ascribed to overwork, but overwork itself is often the result of having to deal with the unreasonable demands of heads who are irrational and lack emotional balance. After dealing with various temperamental types who cause trouble when they are in important positions, Dr. May Smith outlined the attributes of a good head. Assuming that he has the necessary intellectual powers and technical knowledge, the first requirement is a sense of justice—a capacity for asking, not "Am I receiving justice ?" but "Am I giving it ?" A good head must create the knowledge that everyone under him will receive fair treatment. A second quality is vitality, explaining that she meant not physical exuberance, which is often exhausting to subordinates, but the controlled energy that inspires them. "The 'Weary Willy' and the 'Streak of Misery'," she said, "should have no place at the head." The next requisite is the ability to regard people and things dispassionately, to see them as they really are, and not merely as they happen to appeal to the man himself. A sense of humour is the next requisite, to prevent the head taking himself too seriously. Finally, the good head must be able to rule without straining his powers on one hand or shirking responsibility on the other. Temperamental factors in industry do not receive sufficient attention in Great Britain, and it is a pity employers and departmental managers do not receive training in handling personalities. 'Nagging' might well be made a capital offence !

The Government Laboratory

FEW, apart from those who study the annual report of the Government Chemist, are well acquainted with the character and volume of the work which is carried out at the Government Laboratory. A detailed and illustrated account of the activities of this laboratory has recently been published in the *Chemist and Druggist* ; since much of the information which relates to processes and figures has been supplied to the author, the article can be accepted as an accurate and fully informed review. The Department of the Government Chemist, in its capacity of a protector of the revenue, undertakes the routine analysis of large numbers of samples of dutiable goods, handling, for example, some 5,000 samples of tobacco every week. As a public servant assisting in suppressing adulteration, it acts as a referee when reports of public analysts are challenged. The samples concerned have frequently undergone changes by the time they reach the laboratory—this applies particularly to samples of milk—so that the necessary analytical procedure is much more elaborate than normally. Such considerations involve a good deal of research, leading to the working out of satisfactory analytical methods. Another function

of the Department is that of acting as an adviser to the State on chemical matters, of taking part in international studies on the mass-movement of the sea from place to place, and of examining samples submitted by other Government departments. In addition to the principal laboratory at Clement's Inn Passage, other laboratories under the control of Sir Robert Robertson are the Custom House laboratory, and laboratories at the Geological Survey, at the Army Supply Depot at Deptford, at Park Royal, and at five seaports. The public thinks of these laboratories as places where a great deal of 'testing' is carried out; chemists, however, know that in addition they house a vigorous research organisation, only part of the work of which can, in the public interest, be published in the scientific journals as notable contributions to the common stock of chemical knowledge.

Harrison's Chronometers at the Science Museum

THE Admiralty has kindly lent to the Science Museum, South Kensington, all four of the pioneer marine timekeepers made by John Harrison between 1729 and 1759. With these instruments Harrison was the first to show that it was possible to construct a portable timekeeper which would keep sufficiently accurate time at sea to be of use in determining a vessel's longitude, and thus solved the problem of 'finding the longitude' which had baffled men of science and inventors for more than two hundred years. Harrison's instruments were the first balance-wheel timekeepers to embody any kind of compensation for the effects of change of temperature. In all four of his instruments compensation is provided by varying the effective length of the balance-spring, the mechanical details varying in the different individuals. In the first three timekeepers, the effect of the ship's motion is also compensated by employing two balance-wheels connected together by an ingenious but delicate system equivalent to a frictionless gearing; in the fourth chronometer, however, this system is abandoned in favour of a single small balance-wheel the angular acceleration of which is large compared to the stray accelerations due to the ship's motion. The first three chronometers are large clocks each weighing more than fifty pounds, but the fourth is much smaller, being essentially a large watch about five inches in diameter. All four instruments have been cleaned, repaired and put into working order by Lieut.-Commander R. T. Gould, and they are now on exhibition in the Museum, in going condition.

National Park in Snowdonia

SIX months ago public interest in Snowdonia as a national park was revived by the offer made by Mr. C. Williams-Ellis to the National Trust of 300 acres near Nant Gwynant with covenants to preserve the rest of Hafod Lwyfog farm in its present condition, provided others would co-operate in taking further steps for the preservation of this beautiful area. Since then the Caernarvonshire County Council has taken active steps towards the preparation of a planning scheme covering the whole area. Now, through the generosity of an anonymous benefactor, a scheme has been formulated by the National Trust for the preservation of the Aberglaslyn Pass. The anonymous benefactor has provided the funds for the purchase from the Snowdon Mountain Railway, Ltd., of the east side of the pass, provided the Trust can secure the co-operation of the owners of the land on the west side. The owners of Plas Aberglaslyn on the west of the Pass and Mr. Clough Williams-Ellis as owner of a small area to the south have immediately agreed, and the National Trust is now confidently awaiting the assurances of one or two other contiguous owners before completing the purchase. It is further believed that another offer of land between Gwynant and Pont Aberglaslyn is likely to be made.

Medical Botany of the Eighteenth Century

MR. H. S. REDGROVE contributes an interesting article to the *Gardeners' Chronicle* of May 11 describing a very complete work on "Medical Botany, containing Systematic and General Descriptions, with Plates, of all the Medicinal Plants, indigenous and exotic, comprehended in the Catalogues of the Materia Medica, . . . accompanied by a Circumstantial Detail of their Medicinal Effects, and of the Diseases in which they have been most successfully Employed". This remarkable work was from the pen of Dr. William Woodville (1752–1805). It was published first in monthly parts, but later in three volumes and a supplement (1790–94). Woodville's life is described briefly in the article under review, and his peculiar qualifications for the work are emphasised. One cannot but feel regret, as Mr. Redgrove quotes passages from "Medical Botany", that such herbs as *Potentilla erecta* have passed from medicinal use, for their employment seems to have been determined by very exact knowledge. 210 drawings by Sowerby were included in the work, which was written in a thoroughly scientific spirit.

Common Names for Plant Diseases

DIFFICULTIES of expression by written word are great, even when words have exact literary meanings. The words of a new science like plant pathology have been coined by practical growers in different places and under varying conditions, so it is not a matter of wonder that much confusion has resulted. The second edition of the "List of Common Names of British Plant Diseases" (Cambridge: University Press. Pp. 95. 2*s*. 6*d*. net) represents a serious attempt to standardise nomenclature of disease symptoms and causal agents. It has been compiled by the Plant Pathology Committee of the British Mycological Society. The list is in two columns—first the common name and then the name of the parasite. Synonyms are given where necessary, but the volume is a well-regulated attempt to establish one name for each disease. Many synonyms are being discouraged, whilst in one or two cases fresh names have been introduced for the sake of clarity. The host plants are grouped conveniently into

vegetables, cereals, fruit, ornamental plants, etc., whilst the causal agents are listed in the order—Viruses, Bacteria, Myxomycetes, Phycomycetes, Ascomycetes, Basidiomycetes, Fungi Imperfecti, and Non-parasitic. Foreign names are also given where possible. The comprehensive orderliness of the list should commend it for universal adoption.

Acta Physicochimica U.R.S.S.

THE publication of the *Acta Physicochimica U.R.S.S.* commenced in September 1934, and volume I containing six parts has just been completed. In Russia as in other countries, the ramifications of chemistry, especially in its mathematical and physical aspects, are growing so complex and varied that it is found desirable to have as a medium for publication, in addition to the usual journals devoted to chemistry, a special one devoted to the more advanced aspects of physical and theoretical chemistry. We have noted the recent appearance of the *Journal of Chemical Physics* in the United States, the remarkably effective and somewhat sudden renaissance of the *Transactions of the Faraday Society* in Great Britain, and now the appearance of the *Acta Physicochimica* in Russia. The board of editors of the journal is certainly to be congratulated on the first six parts. It would appear that the referees appointed by the board function admirably in that country in selecting suitable—and presumably also in rejecting unsuitable—material. A number of internationally well-known names, including those particularly well known in England, Profs. Frenkel, Frumkin, Rabinovitch, Semenoff and Talmud, are to be found on the board, and there is a list of some forty permanent contributors distributed over seven cities of the U.S.S.R. Although new journals furnish problems both in budgeting and in library accommodation, these difficulties will be overcome at least for this admirable example of a specialised scientific journal.

Insects of Samoa

THE British Museum (Natural History) has recently issued further instalments of the publication entitled "Insects of Samoa", a work which has been noticed from time to time in these columns. Part 6, Fasc. 8 of the complete work, by Mr. J. R. Malloch, of the U.S. Bureau of Biological Survey, deals with some further groups of Acalypterate flies, namely, the families Drosophilidæ, Ephydridæ, Sphaeroceridæ and Milichiidæ, and is illustrated by 16 text-figures. In Part 6, Fasc. 9, Mr. Malloch discusses certain families of Cyclorrhaphous flies, namely, Phoridæ, Agromyzidæ, Micropezidæ, Tachinidæ and Sarcophagidæ (supplement). Dr. H. H. Knight, of the Iowa State College, deals with the hemipterous families Miridæ and Anthocoridæ (Part 2, Fasc. 5), which comprise 21 genera and 33 species. Part 3, Fasc. 4 is by Mr. W. H. T. Tams of the British Museum (Natural History), who contributes a lengthy section comprising all the Heterocera, excepting the Geometridæ and Microlepidoptera, which have already been reported upon. Mr. Tams's report more than trebles the number of Samoan moths represented in the British Museum. It also contains important observations on nomenclature and upon the grouping of the subfamily divisions of Heterocera.

Field Museum of Chicago

THE economic situation in the United States is bearing heavily upon institutes such as museums which depend largely upon the goodwill and financial aid of the people. The annual report for 1934 of the Director of the Field Museum of Natural History shows this clearly. Income, from endowments, tax collections, admissions and membership, was in each case reduced, so that a total of 491,002 dollars stands against 636,318 for 1933. Visitors have fallen from more than three millions in 1933 to less than two millions in 1934, though the earlier year's numbers were abnormally increased by the opening of the "Century of Progress Exposition" in Chicago. In spite of difficulties, the Field Museum continues to prosecute research in various fields, though these are now limited to privately financed expeditions; it has added notable groups of animals to its public galleries; and it continues by means of lectures (attended by some 662,000 persons, mostly children) and by travelling natural history exhibits (to more than four hundred schools) to educate the youth of Chicago biologically.

Examinations in Milk Processing and Control

THE City and Guilds of London Institute has arranged to hold examinations in the future, commencing May next year, in milk processing and control, with certification of successful candidates. It is hoped that the provision of the examinations will encourage the formation of classes of instruction in these subjects in different parts of Great Britain, so that those engaged in the milk industry who receive such instruction should be in a position to render more efficient service. It is proposed that the examinations should be held at approved centres in Great Britain, Ireland and overseas. The syllabus of the examination for the certificate, which will be in two parts, intermediate and final, has been drawn up by a representative advisory committee, and may be obtained from the Superintendent, Department of Technology, City and Guilds of London Institute, 31 Brechin Place, South Kensington, London, S.W.7.

The Seismological Station of De Bilt

WE have received the valuable report on the earthquakes recorded at this well-known observatory during the year 1932. The instruments include horizontal and vertical component Galitzin seismographs and also Wiechert and Bosch seismographs. In addition to a catalogue of 437 earthquakes, the report contains an appendix on the earthquakes in North Brabant during November 20–28, 1932. The principal earthquake occurred on November 20 and was felt all over the Netherlands, in Belgium and west Germany, and even, it is said, in London. Its epicentre (in lat. 51° 40′ N., long. 5° 35′ E.), as well as the epicentres of three strong after-shocks, lay close to the boundaries of the central rift-valley.

T. K. Sidey Summer-time Award

It is announced that the second award of the T. K. Sidey Summer-time Medal and Prize will be made by the Royal Society of New Zealand at its annual meeting in May 1936. The award, which comprises a medal and a prize of £100, is made for the most valuable contribution or contributions to human knowledge by research in the study of light visible and invisible and other solar radiations in relation to human welfare. Applications will close with the Secretary of the Society on February 29, 1936. Theses specially prepared or copies of published works may be submitted. The first award of this medal was made to Lord Rutherford in 1933.

Melbourne Meeting of the British Medical Association

The annual meeting of the British Medical Association will be held in Melbourne on September 9–14, under the presidency of Sir James Barrett, deputy chancellor of the University of Melbourne. The meeting will be divided into the following sections, with the sectional presidents indicated: Medicine, Lord Horder; Surgery, Sir Thomas Dunhill; Obstetrics and Gynæcology, J. S. Fairbairn; Radiology and Radiotherapeutics, H. M. Moran; Diseases of Children, Dr. Robert Hutchison; Neurology and Psychological Medicine, Prof. E. Bramwell; Ophthalmology, Dr. A. J. Ballantyne; Orthopædics, Prof. E. W. Hey Groves; Oto-Rhino-Laryngology, Francis Muecke; Pathology and Bacteriology, Prof. A. M. Drennan; Pharmacology, Therapeutics and Anæsthesia, Sir William Willcox; Public Medicine, including History of the Development of Medicine in Australia, Sir Henry Gauvain; Dermatology, Dr. S. Watson Smith; Medical Sociology, Dr. E. Kaye Le Fleming. The honorary local general secretary is Dr. J. P. Major, Medical Society Hall, Albert Hall, East Melbourne, C.2.

Announcements

Dr. E. J. Butler, director of the Imperial Mycological Institute, has been appointed secretary to the Agricultural Research Council, in succession to Sir William Dampier. Sir William will be appointed a member of the Council as from the date of his resignation of the secretaryship on September 30.

The Medical Research Council has awarded Dorothy Temple Cross Fellowships for the academic year 1935–36, under the terms of the benefaction in that name for research fellowships in tuberculosis, to the following:—Dr. G. B. Brook, senior assistant veterinary officer, Derbyshire County Council; Dr. J. W. Craig, assistant medical officer, King Edward VII Sanatorium, Midhurst, Sussex; and A. H. B. Rhodes, house physician, Brompton Hospital, London.

Busts of Robert Koch and Conrad Röntgen have recently been placed in the Deutsches Museum at Munich on the occasion of the tenth anniversary of its foundation.

Among various other works of anti-aircraft defence, the Municipality of Prague has decided to build a subterranean hospital containing several hundred beds.

Dr. Arthur Meyer, head of the publishing firm of Johannes Ambrosius Barth at Leipzig, has been awarded the Goethe Medal by the German Chancellor in recognition of his services to German scientific literature. He has also been made a doctor *honoris causa* by the medical faculty of the University of Leipzig.

The German Society of the History of Medicine, Natural Science and Technique will hold its annual meeting at Bamberg on August 29–September 2. Further information can be obtained from the secretary, Dr. Walter Artelt, Institut für Geschichte der Medizin und Naturwissenschaften, Universitätsstrasse 36, Berlin, N.W.7.

Applications are invited for the following appointments, on or before the dates mentioned:

A chief lecturer in engineering in the Bournemouth Municipal College—The Director of Education, Town Hall, Bournemouth (Aug. 17).

A technical officer in the Meteorological Office—The Secretary (S. 2. E.), Air Ministry, Adastral House, Kingsway, W.C.2 (Aug. 22).

An inorganic chemist on the staff of the British Scientific Instrument Research Association, 26, Russell Square, London, W.C.1—The Director of Research (Aug. 23).

A lecturer in mathematics in the University of Reading—The Registrar (Aug. 26).

Lecturers in mechanical engineering and mining engineering in the Denbighshire Technical Institute, Wrexham—The Director of Education, Education Offices, Ruthin (Aug. 26).

A dairy bacteriologist at the County Council Farm, Hutton, near Preston—The Director of Education, County Offices, Preston (Aug. 30).

An assistant lecturer in zoology in the University of Leeds—The Registrar (Aug. 31).

An assistant Government analyst in the Straits Settlements—The Director of Recruitment (Colonial Service), 2 Richmond Terrace, Whitehall, S.W.1 (Aug. 31).

A secretary to the Institution of Naval Architects—Council, Institution of Naval Architects, 2 Adam Street, W.C.2 (Aug. 31).

A head of the Engineering Department and the Junior Technical School, Municipal Technical College, Blackburn—The Director of Education, Education Offices, Blackburn.

A dairy instructor at the Farm Institute, Sparsholt, near Winchester—L. G. Troup, Agricultural Organiser, 82 High Street, Winchester.

A municipal engineer at Jaffa—Crown Agents for the Colonies, 4 Millbank, Westminster, S.W.1, quoting M/3786.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 226.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Dentition of *Ornithorhynchus*

IN 1888 Poulton, when examining some sections of the head of a young platypus, made the very important discovery of true calcified teeth. In the upper jaw he found evidence of four teeth, and he believed that four would also be found in the mandible. He also says: "I think that it is probable that the rudiments of teeth may be found anterior at a much earlier stage".

Oldfield Thomas and C. Stewart showed soon after Poulton's discovery that the calcified teeth are functional until the platypus is about half-grown.

In 1907 Wilson and Hill, by the study of two stages earlier than Poulton's specimen, added much to our knowledge of the developing teeth. They found evidence of four upper and five lower teeth, and also of a small calcified tooth of an earlier set than the functional teeth—clear evidence of a dental succession.

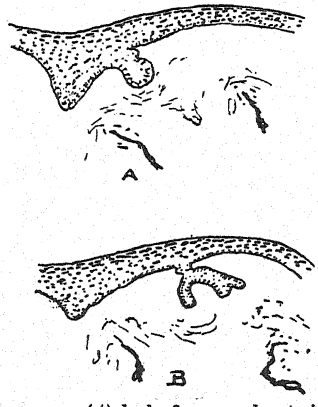

FIG. 1. Sections across (*A*) bud of supposed anterior lower incisor, (*B*) enamel organ of supposed lower canine, in very young *Ornithorhynchus*. × 80.

I have recently been examining sections of the head of a stage a little older than Wilson and Hill's younger specimen, and have just discovered a few interesting new facts. In what may be called the molar region, there seems little doubt that there is evidence of six teeth in both the upper and the lower jaws. Following the nomenclature of Wilson and Hill, these may be called *u*, *v*, *w*, *x*, *y* and *z*, and the functional teeth of the adolescent animal are *w*, *x*, *y* above and *x*, *y*, *z* below. Connected with *v* above and below there is clear evidence of a tooth of an earlier set, as found by Wilson and Hill, and I think the condition of the epithelium at the necks of *w* and *x* show indications of a *dw* and *dx* both above and below.

The most interesting discovery I have made, however, is some anterior teeth which have not, so far as I can learn, been previously seen.

In the upper jaw there is no dental lamina or any indication of teeth in front of the tooth germ *u*. But in the lower jaw in front of *u* we have a short distance with no dental lamina, and then an anterior portion of dental lamina with apparently the germs of three teeth. As might be expected in dealing with rudimentary structures, there is a slight difference in the two sides. On the right side the most anterior germ, which may be called *a*, is a well-marked little dental bud. Behind it is a second, *b*, and then we have a much better tooth germ *c*. This latter has quite a distinct enamel organ. On the left side, the tooth germ *a* is less developed and the tooth *c* a little better developed.

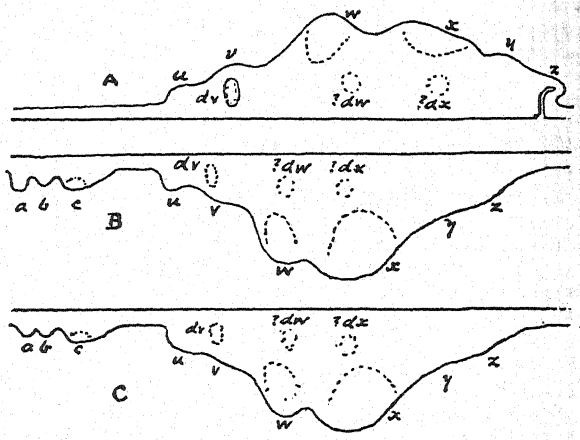

FIG. 2. Reconstruction of the dental laminæ of young *Ornithorhynchus*, length from snout to tip of tail about 90 mm. Dental laminæ of (*A*) upper jaw, (*B*) right mandible, (*C*) left mandible (reversed). × about 40.

These anterior teeth cannot, I think, belong to the premolar or molar set, and are evidently either three incisors, or more probably two incisors and a canine.

Fig. 1 includes a section through the right *a* and the right supposed canine. It will be observed that in the canine there is evidence of the dental lamina in addition to the enamel organ, and there is also evidence of the dental lamina by the side of the rudimentary supposed incisors. So that it seems probable that, in the case of both the supposed incisors and canine, there has been a dental succession in the ancestor.

The full dentition of *Ornithorhynchus* seems to be:

$$i\,\frac{0}{2}\,c\,\frac{0}{1}\,pm\,\frac{4}{4}\,m\,\frac{2}{2}.$$

This evidence does not help us very much towards the solution of the problem of the affinities. But it seems to show that *Ornithorhynchus* is descended from a form which had a full dentition, such as an Ictidosaurian or a Pantothere, rather than from a Multituberculate which had early lost the canines.

Transvaal Museum, R. BROOM.
Pretoria.

Induced Radioactivity of Fluorine and Calcium

In an earlier paper[1], I have shown that sodium and phosphorus become radioactive under bombardment with alpha rays, presumably corresponding to the creation of Al^{26} and Cl^{34} respectively. In the case of phosphorus, chemical separation of the active body, kindly carried out by Prof. S. Sugden, gave strong support to this picture. Between these two unstable isotopes lies a third one, P^{30}, found by Curie and Joliot[2]. It was pointed out that another link of that chain, Na^{22}, should be produced by bombarding fluorine with alpha rays. Since the periods of the three above-mentioned bodies decrease rapidly with atomic number, a very short period was anticipated for Na^{22}. The search for this substance was unsuccessful, however, although periods so short as one tenth of a second would have been detectable by the method applied.

About that time, the emission of positrons from fluorine under alpha-ray bombardment was reported in a paper by L. Meitner[3]. The positrons were observed only during bombardment, and no life period was given. This was generally taken as evidence for a very short period. However, the very low energy of the positrons, as measured by Meitner, rather seemed to point to a long period. On inquiry, I was kindly informed by Prof. Meitner that no attempt at all had been made to measure the period, simply because the experiments had been carried out before the discovery of induced radioactivity. I have therefore recently taken up the search for an isotope Na^{22} of long period.

Through the courtesy of the Committee of the Radium Institute and Finsen Hospital, I was enabled to use radon in quantities up to 600 millicuries as the source of alpha rays. The radon was put into small glass vessels with a thin mica window which reduced the range to about 6 cm. Upon bombarding calcium fluoride, fairly strong effects were obtained at once; other calcium compounds, however, gave similar effects. The search for Na^{22} was therefore continued with sodium fluoride and lithium fluoride. In both cases weak activity was observed after prolonged bombardment. A chemical separation, kindly carried out by Prof. G. von Hevesy, showed that the active body follows the reactions of sodium, and therefore is presumably Na^{22}.

In striking contrast with the first anticipations, the outstanding feature of this new activity is its long period. One sample has been under observation for three weeks, with no evidence of decay. It may be concluded that the half-period must be at least six months. This explains the apparent weakness of the effect; indeed, with a few days' bombardment, only a fraction of the equilibrium activity is obtained. On the other hand, a reasonable assumption about the equilibrium activity leads to an estimated life of from one to several years.

The particles emitted from Na^{22} were shown by magnetic deflection to be positrons. They are rapidly absorbed in aluminium, the half-value thickness being about 0·03 gm./cm.^{2}. This corresponds to a mean energy of about 2×10^5 electron-volts, in good agreement with the results of Meitner.

The activity produced in calcium has also been studied. The half-period is 4·4 hours, with a possible error of ten per cent. The particles emitted are positrons, and their half-value thickness of aluminium is about 0·06 gm./cm.^{2}. From the great intensity, one may say that the effect is due to the main isotope of calcium, Ca^{40}. Capture of the alpha particle, with subsequent emission of a proton or neutron, would lead to the formation of Sc^{43} or Ti^{43}, respectively. A chemical separation, kindly carried out by Prof. G. von Hevesy, showed that the active body follows the reactions of scandium. Therefore the 4·4 hours activity certainly corresponds to Sc^{43}. Of course, it cannot be excluded that in the first instance Ti^{43} may be formed, and quickly transformed into Sc^{43} by emission of a positron. No short-period activity, however, could be detected.

The Rate of Photosynthesis

The recent correspondence on photosynthetic rates[1,2,3] has emphasised numerous significant facts now known about the process. A few important ones still remain. They can be roughly summarised by saying that the equations proposed seem to contain no term for the plant.

In the proposals of Burk and Lineweaver[2] the symbol (CO_2) is used without qualification, and the authors say that their equation provides for hyperbolic relations between y (rate) and (CO_2) "in accordance with experiment". Presumably, therefore, (CO_2) is to be read as the external and measurable concentration of carbon dioxide. But this cannot be the effective concentration in their reaction (I)

$$\text{Chl} + CO_2 \rightleftarrows \text{complex}.$$

I have been able to show[4] that the rate of photosynthesis can be made to vary considerably when all other conditions are kept constant and only the method of supply of carbon dioxide varied. Shortening the external diffusion path increases the rate, but there always remains the distance (measurable in μ) between the outer cell surface and the chloroplast. With moderate carbon dioxide concentrations and intensities of light, this is never negligible[5]; moreover, even the conception of a constant concentration right up to the cell surface is entirely 'ideal' and not realised with any plant. Allowing for these conditions, the equation

$$C_e = \frac{RK'}{A-R} + dR$$

will give a close fit to the observed rates, where C_e is the initial external concentration; R the rate; K' the dissociation constant of the chlorophyll-CO_2 complex; A, a constant independent of C_e, but varying with light, and d a resistance term including, but probably not solely depending on, the resistance to hydro-diffusion. The full derivation of this equation I have already given elsewhere[6].

A further difficulty resulting from structural considerations occurs in the absorption of light. A linear relation between light intensity and rate of the primary photochemical reaction may be a permissible approximation in simple cases; but it is more doubtful whether we are entitled to carry over this assumption to a wide range of plants with their exceedingly complex light-absorbing surfaces. We are here also faced with a complication, first

pointed out, I believe, by G. E. Briggs[7]. It is highly improbable that photosynthesis depends on a single photo-reaction of unit quantum efficiency, since it would appear that there is no quantum in the visible spectrum large enough to meet the minimal energy requirement. Experimental measurements[7,8] indicate a possibility of a value as low as 0·2 for the overall reaction. It seems to me that we must, therefore, assume either a photo-reaction not obeying the Einstein rule, or a series of n photo-reactions (n might be as high as 5), or a gain of energy in a thermal reaction. Since the great bulk of the light falling on a leaf is transformed to heat, there is no difficulty about a source of such energy. The first two of these alternatives certainly would, and the third might, necessitate changes in the proposed schemes.

It is impossible to contemplate this field of work without wondering whether the present position justifies the application of some of the kinetic assumptions employed. Realising the approximations and 'idealisations' inevitable, it is amazing that prediction gets as near the truth as it sometimes does. In such complicated systems the possibilities of errors compensated into rough agreements appear manifold. Recent careful work[9] even makes doubtful the existence within the plant of the 'steady states' which are the very basis of the analyses quoted by the correspondents in NATURE. It is clear that 'diffusion', 'reaction' and other 'constants' cannot here be given their usual significances, if only because they differ from plant to plant. It would appear that much pedestrian work on specific plants remains to be done before we can approach accurately based semi-quantitative generalisations.

Thermal Decomposition of Ozone

RECENTLY, H. J. Schumacher[1] has given his reasons for regarding the interpretation of the results obtained by me[2] as incompatible with the findings of other investigators. The essential difference between these results[2] and those of Glissmann and Schumacher[3] lies in the absolute rates of decomposition. It is possible that in the vessel employed, part of the measured decomposition was due to surface activation, the ratios of rates for the different temperatures yielding an apparent heat of activation (19,000 cal.) less than the recognised endothermic heat of reaction of the gas reaction (24,000 cal.). The 'inert gas' effects, however, both accelerating and retarding, can scarcely be related to a surface decomposition in itself, but must be gas phase processes.

The calculation of the heats of activation Q_2 (reaction $O + O_3 = 2O_2$) and Q_3 ($O + O_2 + O_2 = O_3 + O_2$) from my data was based on the assumption that the number of effective collisions was given by $Ze^{-E/RT}$, the steric collision factor being taken as unity. The values thus obtained are maximum values; correspondingly, if the heat of activation of the ternary collision is zero, the heat of activation of the secondary reaction is 9,000 cal. The correspondence between this figure and that cited by Schumacher from photochemical data (5,000 cal.) was taken as support for the oxygen atom theory, in view of the fact that the former value was calculated on principles of diffusion not involved in the photochemical decomposition.

The region in which the postulated diffusion effect can be experimentally realised is a small one, determined by temperature as well as by pressure and vessel dimensions. The interpretation of the present results is not regarded as incompatible with the photochemical decomposition from this point of view.

It appears from the summary of Schumacher[4] that the possibility of reaction chains involving excited oxygen molecules depends largely on the nature of the oxygen atom, in the sense that the excited oxygen atom produced by photo-dissociation of ozone by light of short wave-length is more likely to start a chain than is the normal unexcited atom. When the heat of activation is close to the endothermic heat of reaction, one cannot deduce with certainty that a chain mechanism must play a large part in the thermal decomposition. Since my experiments were carried out with pressures of ozone not greater than 100 mm., and for the most part in the presence of nitrogen which would presumably tend to deactivate excited oxygen molecules, the possibility of reaction chains playing a prominent part in the decomposition in such circumstances is regarded as a small one.

The Free n-Propyl Radical

THE clean fission of the lower aliphatic ketones effected by ultra-violet light led us to examine the symmetrical di-n-propyl ketone with the object of preparing the n-propyl radical.

We allowed the ketone to stream through a transparent silica tube, and irradiated it over a restricted area with the unfiltered light from two quartz mercury vapour arcs. Free radicals were produced, and rapidly removed metallic mirrors situated 10 cm. from the nearer edge of the illuminated zone.

The volatile products resulting from the action of the radicals on mercury were passed into mercuric bromide, the excess of ketone distilled off, and the solids subjected to fractional sublimation in a vacuum. The three head fractions melted at 137°–138° (mercury n-propyl bromide, m.p. 138°)[1]. The melting point of the fourth fraction was not depressed by admixture with an authentic specimen of mercury n-propyl bromide.

It is thus concluded that di-n-propyl ketone is decomposed in ultra-violet light with the formation of free n-propyl radicals.

Units and Symbols

THIS letter is intended to be provocative. A volt (or ampere) is denoted V (or A): a millivolt (or milliampere) mV (or mA): a microvolt (or microampere) μV (or μA). A farad is known as F, a microfarad as μF (though misguided people write it mfd. or mF., which, if anything, should mean millifarad): a micromicrofarad (10^{-12} farad) is μμF. A millihenry is mH, a microhenry μH. A gram is g., a milligram is mg., but some (and not the least worthy) biochemists use a symbol which few others understand, and call a microgram not μg. but γ. A second (of time) has the symbol sec. (not ″): a millisecond is msec.: a microsecond is μsec. Why do physiologists (and they alone) persist in using the symbol σ to represent, not—as it might less unsuitably do in view of μ and γ—a microsecond, but a millisecond? And why are they permitted, instead of writing 7 msec. (which others could understand) to use 7σ, or 7 sigmas (in America) or 7 sigmata (in Oxford)?

A metre (not meter) is m. (m means milli): a millimetre is mm.: a micrometre (not micrometer!) is μm., a micron or by courtesy μ. A millimicron therefore is mμ, a micromicron is μμ. It is all quite simple, yet otherwise law-abiding people (physicists this time, who ought to know better, not physiologists or biochemists) call a millimicron a μμ (see E. N. da C. A., "Encyclopaedia Britannica", 14th edition, Vol. 18, p. 874) or apply the same symbol to the same thing, now called a "micromillimetre" (Vol. 17, p. 877) which, with this name, is clearly not μμ but μmm. Fortunately milli- and microwatts mean what they say: but 1,000 millibars amount (nearly) to atmospheric pressure, which some people (chemists this time!) insist on calling a 'megabar' (compare megohm, megacycle) because they say that a bar is 1 dyne per sq. cm. Calories (at the beginning of a sentence, or in books on nutrition) may mean either Calories (10^3 cal.) or calories (cal.): it would be just as simple to refer to kilocalories (kcal.) as it is to kilograms (kg.) or kilocycles.

The moral is clear. Let us use our symbols logically and consistently and not make other people's tasks more difficult by inventing pet-names of our own. How can nations be expected to settle their differences, even as to the dates of Summer Time, when we men of science cannot agree on μμ, or bar, or μF, and insist on hiding our meaning by σ's and γ's which are unintelligible to the majority?

Should Scientific Publication be Controlled?

AFTER a delay of many years, the great work (576 pages, 67 plates) on the Caddis flies, by Cornelius Betten, has at last been published by the New York State Museum at Albany. It is reviewed by Dr. C. H. Kennedy in *Annals of the Entomological Society of America*, June 1935. The reviewer remarks: "This much needed volume has finally appeared. The reviewer saw the 'revised' manuscript at Cornell in 1915. It had been practically completed nine years before. Projects of more immediate use to the tax-payer used the Museum funds that had been planned for its publication. One new species after another was scooped by various casual students of the order. The last scoop was accomplished by one who had had the privilege of studying the manuscript and who rushed two papers through by publishing privately after the present volume was on the press."

Deplorable as was the delay, it must be admitted that the so-called casual students of the order were perfectly justified in publishing their work; that it is wholly unreasonable to expect publication on a group of insects to be halted for a quarter of a century because an important monograph has been prepared but cannot be published. When it became obvious that the publication would be indefinitely postponed, the new species should have been published separately. But what is described as the "last scoop" is in a different case. I do not know what it antedates in Betten's work, but I have seen a copy, and it is a much abbreviated summary, just sufficient to validate a number of specific names. It is printed by one of those duplicating machines, now so widely used for class work in colleges. I do not think it can be considered to be merely mimeographed; it seems to represent what must be considered printing in the sense of the rules. It is published privately, but is offered for sale, and the copy I saw, in the library of the California Academy, had been purchased.

A good many years ago, a certain entomologist, a student of parasitic Hymenoptera, printed privately a series of small papers containing descriptions of new species. These he advertised for sale in one of the scientific magazines. I bought a set, which I later divided between the U.S. National Museum and the British Museum. Apparently I was the only purchaser, and the author himself, who had in the meanwhile gone to Australia, lost his own copies, and wrote begging me to return those I had.

All zoologists and botanists are aware of the trouble caused by irregular publications, and of the controversies which have arisen as to what constitutes a publication. The rule requiring that a work must be placed on sale is ambiguous, and not always observed. Thus the splendid memoirs of the U.S. National Academy are not for sale, until they come on the second-hand market. With the newer methods of duplication, as indicated above, anyone can get out a small publication and offer it for sale, though it may not be obtainable through the usual channels, and may be almost unknown.

I have lived to see many taxonomic proposals, at first derided, eventually gain acceptance and become commonplace. I should consider it a great evil if all publication were controlled by the older men, or indeed by any particular group. But it does not seem unreasonable to suggest that certain definite channels for the publication of new taxonomic proposals should be established, and that there should be some control over the manner of these proposals, so that, sound or not, they should be intelligible. It might not be unreasonable to require that a type specimen should be deposited in some museum, where it could be examined. In short, some regulation is evidently needed, and we ought not to be so afraid of unjustifiable interference that we will not do anything. Whatever is done, should have the support of 'common sense', and not merely arbitrary rules. In addition to the matter of publication, we would commend to the International Commission another growing evil, the publication of erratic names. Great liberties have been allowed,

and I think quite properly, but there is a point when a name is so peculiar, or so badly constructed, that it almost suggests a lapse from sanity. There is surely no necessity for these aberrations.

Failure of Fourier Analysis applied to Vowel Vibrations

THE curve in Fig. 1*a* was produced by multiplying each ordinate of the curve $y = a \sin wx$ by the value or the corresponding ordinate of the curve $y = e^{-\delta x}$.

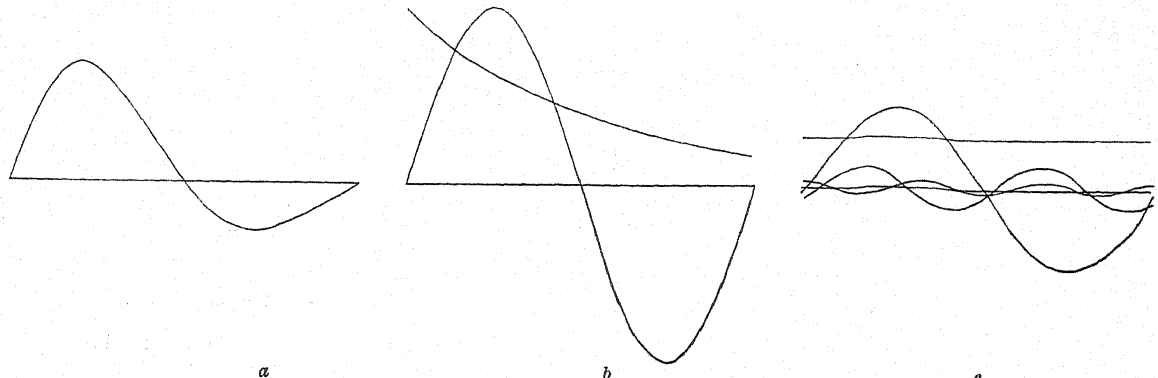

FIG. 1.

The two component curves are shown in Fig. 1*b*. The equation for the curve in Fig. 1*a* is

$$y = ae^{-\delta x} \sin (\sqrt{w^2 - \delta^2})x \qquad (1)$$

The Fourier harmonic analysis produces a constant plus a series of sine functions with pulsatances in the relations 1, 2, 3 . . . and with amplitudes that diminish from a maximum for the first one and continue in ever-decreasing amounts to infinity. The constant and the first three sine functions are shown in Fig. 1*c*. According to this analysis the equation for the curve in Fig. 1*a* would be,

$$y = A_0 + A_1 \sin (x + \theta_1) + A_2 \sin (2x + \theta_2) + A_3 \sin (3x + \theta_3) + \ldots \qquad (2)$$

As a mathematical formula, the result is perfectly correct; as an indication of the character of the curve or of how it was derived, it is a failure. It may be objected that the analysis is not intended to show how the curve was derived; the reply is that this is just what everybody who has applied it to vowel curves supposes that it does.

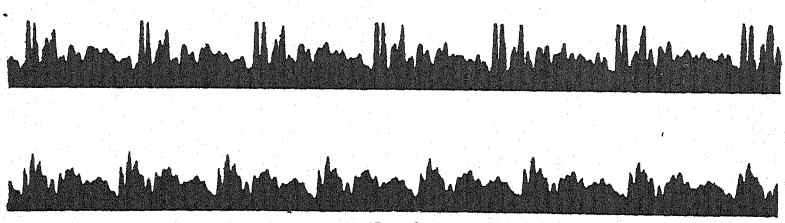

FIG. 2.

Portions of sound film tracks of *a* in *ash* and *oo* in *choo* are reproduced in Fig. 2. Each of them consists of a series of contiguous vibration bits. Each bit contains waves that begin strong and diminish rapidly to zero. The vibrations are plainly affected by strong factors of decrement. If we assume that the curve in a vibration bit is the sum of a series of sine curves, we are entitled to suppose that these sine curves have decrements and are of the character of that shown in Fig. 1*a*. A Fourier analysis, however, produces a long series of sine functions without decrements. The assumption that this indicates the manner in which the vowel vibrations were produced leads to the advocacy of the Wheatstone overtone resonance theory of the vowels, and the rejection of the Willis-Helmholtz-Hermann theory according to which a vowel consists of a series of short free vibrations. A glance at the vowel tracks in Fig. 2, however, is sufficient to show that this latter theory is the one that accords with the facts.

New Methods for Measuring Mechanical Stresses at Higher Frequencies

THE existing methods for measuring mechanical stresses due to vibrations are (with few exceptions, applicable only in special cases) dependent upon special devices clamped to the structure to be examined. For the purpose of measuring stresses due to impact near to the point of impact these methods are generally useless, as the measuring device then makes movements relative to the structure, so introducing errors in the stress record. These errors were examined by me in the case of two stress-recorders of the latest types and were found to be of such serious magnitudes that I had to abstain from using this kind of apparatus in my previous investigations[1].

During my stay at Trinity College, Dublin, I developed two new electrical methods, which are free from these faults.

The first is based on the change in electrical resistance in a specially prepared carbon coating which is directly applied to the surface of the structure to be tested (in the case of a metallic structure, after covering the surface first with a thin insulating layer.) If the underlying surface of such a coating

is stretched, the carbon particles move apart (and vice versa, if the structure is compressed) and so the resistance of the coating changes in the same way as the resistance of a microphone. If the coatings are properly prepared, they behave in a sufficiently stable manner and also give a linear response without hysteresis. An ordinary two-stage amplifier is required to operate a cathode ray oscillograph.

The second method uses a piezoelectric crystal (quartz or Rochelle salt), cemented to the surface of the structure to be examined. If the structure is stretched or compressed, the crystal must follow this deformation proportionally and liberates therefore corresponding charges. If a Rochelle salt crystal is used, a small crystal of a few millimetres dimensions is sufficient to operate a cathode ray oscillograph without the use of any amplifier (it may indeed be necessary to reduce the generated voltage by shunting the crossplates of the oscillograph by an additional capacity). The response of the Rochelle salt crystal has so far been found to be linear and without hysteresis, and it appears that for general purposes no necessity for the use of quartz crystals exists.

The new methods are in every way suitable for the study of impact problems. The second method has the additional advantage that, owing to the minute size of the crystal, it is possible to measure the local value of stress instead of an averaged value. A more detailed account of these investigations will be published shortly.

Graphical Representation of Complex Numbers

A SEARCH of the older texts has revealed an error in the analytical treatment of the graphical representation of complex numbers by Wessel in his original memoir on the subject to the Royal Academy of Denmark in 1797. The error has been perpetuated by many subsequent writers. Wessel, in proposing the representation which we now use, refers explicitly to 'operations' on right lines, and he represents any line, algebraically, by the expression $(a + eb)$, where $+1$ is the unit vector in a given direction and $+e$ a unit vector in a direction inclined to that of the $+1$ vector at an angle of 90°. The $+1$ does not appear explicitly in his analysis.

Wessel goes on to consider the product of 'two right lines'. He says*: "It shall be possible in every case to form the product of two right lines from one of its factors in the same manner as the other factor is formed from the positive or absolute unit set equal to unity". Although written so long ago, this statement describes the present-day conception of the complex number as a *vector operator*.

The product is written by Wessel as follows:

$$(c + ed)\,(a + eb) = ac - bd + e(ad + bc)$$

which is a form to be found in most textbooks. Unfortunately, it contains a serious inconsistency of symbolism. As indicated above, the expression $(a + eb)$, when it appears alone, should be written, strictly, as $(a.1 + b.e)$. Now, the product form, $(c + ed)\,(a + eb)$ or $(c.1 + d.e)\,(a.1 + b.e)$, cannot be interpreted according to the rule just quoted from Wessel, unless we agree to give the symbols $+1$ and $+e$ *operational* interpretations where they occur in the first, or (c,d), factor, and the original unit vector interpretations in the second, or (a,b), factor.

The inconsistency is easily avoided, of course. Let $+1$ and $+e$ have the unit vector interpretations assigned by Wessel, and let any right line (or vector) be written $(a.1 + b.e)$, where a and b are numerics. Without loss of generality we may assume $+1$ and $+e$ to be equal in magnitude. Now, let us put $e = j1$, where the j (or i, if preferred)† is a *rotational operator* that rotates the vector, to which it is applied, through an angle of 90° in the positive direction of rotation.

We may now write:

$$(a.1 + b.e) = (a + jb)1.$$

The expression $(a + jb)$ is a vector operator. It has a dynamic meaning precisely similar to the dynamic meaning of the ordinary number when used as a vector operator with a vector in a uni-dimensional world. In the product form, we write:

$$(c + jd)\,(a + jb)1 = [ac - bd + j(ad + bc)]1$$

and we interpret this, according to the rule given by Wessel, as follows: the operator $(c + jd)$ does to the vector $(a + jb)1$ what the operator $(a + jb)$ does to the unit vector, $+1$. The rule is easily justified from the definition of j and by the acceptance of the symbolic representation employed above; j is then identified with the number $\sqrt{-1}$.

In practice, the unit vector is omitted from most textbooks, and the expression $(a + jb)$ is called a vector. Herein lies a stumbling-block for many students who are not mathematical specialists—and, perhaps, for some who are!

The error does, in fact, amount to a serious inconsistency in nomenclature and symbolism, and attention is directed to it in the hope that textbook writers may help to clarify the position in future editions of their books.

July 3.

* From the translation of the original paper given in D. E. Smith's "Source Book of Mathematics".

† Were it not for the present use of i by mathematicians, it would be better, in the following expressions, to use i as an 'identity' operator, and so write $(a + jb)$ as $(ia + jb)$ or $(ai + bj)$.

Photographs of Bright Meteor Trail of March 24, 1935

ON Sunday, March 24, 1935, between 19.05 and 19.30 G.M.T. a bright meteor trail was seen from the greater part of Holland in a north-westerly direction.

According to some observers, the trail was formed by a very luminous fire-ball, falling nearly perpendicularly to the earth. In about five minutes the white trail assumed strange forms, showing in this manner great differences in wind velocity in the higher levels of the atmosphere.

Mr. van Stralen, at Grouw (Frisia), had the good fortune to photograph this phenomenon, and we are glad to be able to give here (Fig. 1) an enlarged

reproduction of his very rare photograph (19.10 G.M.T.; exposure time, 3 minutes; diaphragm $f/4{\cdot}5$; $f=14{\cdot}6$ cm.). Mr. Groenewold, at Bedum, also obtained two photographs of different phases, reproduced in Fig. 2 (*A*, between 19.00 and 19.05 G.M.T., *B*, between 19.10 and 19.15 G.M.T.; magnification, 10; exposure 20 seconds; diaphragm $f/6{\cdot}3$; $f=10$ cm.).

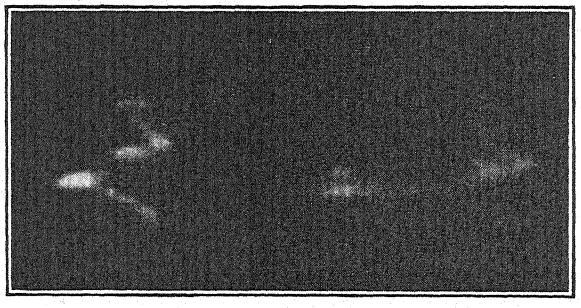
From the *Astronomische Nachrichten* we learn that the phenomena was also seen in north-west Germany,

FIG. 1. Meteor trail of March 24, 1935, photographed by Mr. van Stralen at Grouw.

and Prof. C. Størmer (Oslo) informed us that he received very many observations from Denmark and Norway.

Mr. van Stralen's photograph, and some exact observations from other places, have enabled us to calculate the approximate position of the trail.

For Grouw (53° 5′ N., 50° 49′ E.) the azimuthal direction of the most luminous part was N. 60° 59′ ± 9′ W. The distance from Grouw is about 500–520 km., which gives a position over the North Sea, near



A *B*

FIG. 2. Meteor trail of March 24, 1935, photographed by Mr. Groenewold at Bedum.

the coast of southern Scotland. The height above sea-level of the luminous part must have been 70–75 km. as deduced from the photograph, and from the time at which the light of the trail disappeared, being the moment of sunset for the reflecting particles high up in the atmosphere. Low and medium clouds did not permit any observation in the British Isles. Also the illumination of the sky was perhaps too great.

The movement of the trail was apparently very slow; from some observations we deduce that the wind direction in this high layer must have been from the east.

Ventilation and Domestic Heating

IN a note on domestic heating (NATURE, July 6, p. 16) it is said, "We do not agree with Prof. Bone that a chimney is necessary for the suitable ventilation of bed and living rooms", and add, "Many systems for ventilating rooms have been devised". Now, the nature of the radiations which are used to heat a room have been shown to be of much importance. Dark and dull red heat, in the absence of cool moving air, give stuffy feelings and by congesting the nasal membrane lessen the air-way, as proved by me and confirmed by Dr. W. A. R. Thomson, and by Dr. Dishoeck of Groningen, while bright sources have the opposite effect in about 50 per cent of those observed.

Some people are very sensitive to the quality of radiations, detest dark and dull red sources of heat, and feel a need for open air. It is necessary then that in rooms where electric heating is installed the ventilation should not be just left to an air brick as in the case of some flats now being built for those who are poorly off. Moreover, the air brick may be stopped up, and the electric heater replaced by an oil stove, and the tenants then live in an unwholesome atmosphere. We know that with insufficient ventilation 'droplet' infection becomes much greater. The chimney always secured an unseen ventilation, and allowed of alternative methods of heating. It is, I think, wrong to take this advantage away. We usually lose vigour in winter owing to our stuffy heated rooms, which give us the greenhouse effect in place of sun and cool air. We should not intensify the mischief; and where electric heating is used and no flues built, an efficient means of artificial ventilation would have to be added.

LEONARD HILL.

I THINK that most people prefer a cheerful glow to a dark or a dull red heat. Experiments have recently been carried out by the Department of Scientific and Industrial Research and the Medical Research Council (see *World Power*, **20**, 229–304, Dec. 1933) to inquire into Sir Leonard Hill's statements on the 'nose opening' rays due to bright incandescent sources such as lamps, coal-fires and modern gas fires, and the 'nose closing' rays due to non-luminous sources. No evidence was obtained that any difference on 'nose opening' is due to the temperature of the source, either bright or dull, but 'nose-closing' rays were found with the clinical gas lamp specially recommended by Sir Leonard Hill. The conclusion is reached that nose-closing is due to rapid heating of the skin and is independent of the quality of the radiation.

I entirely agree with Sir Leonard Hill's remarks on ventilation. Unfortunately, it is not cheap, but its cost is only a fraction of what would be saved by building houses without chimneys.

THE WRITER OF THE NOTE.

Relation of *Botrytis* spp. to the 'Chocolate Spot' Disease of Beans (*Vicia Faba*)

In view of the considerable losses in bean crops sustained by farmers in parts of England and Wales during the present season, it appears expedient to summarise the present position of our knowledge of 'chocolate spot' disease.

Chocolate spot disease may attack both broad and field beans, and is characterised by the appearance of chocolate brown lesions on the shoot system. Sardina[1] has described two diseases of beans in Spain which he attributed to distinct species of *Botrytis*. One of these diseases is probably identical with 'chocolate spot'. Ikata[2] considers that *Botrytis Fabæ*, Ikata, is responsible for the disease in Japan. Nattrass[3] has just reported that a species of *Botrytis* is responsible for the disease in Cyprus.

Work has been carried out on all aspects of this disease at Cambridge since 1931 under the direction of Mr. F. T. Brooks. As early as April 1933, experiments carried out at the Cambridge Botany School showed conclusively that several forms of *Botrytis* are responsible for the major part of the disease in Britain, but full publication of the results of these investigations will be delayed.

In the field the disease may assume two forms: (1) a lethal attack resulting in blackening and death of a part or the whole of the shoot system, (2) a non-lethal attack resulting in 'chocolate spot'. Both types of attack have been reproduced by artificial infection in field plots.

Chocolate discoloration of bean shoots is also caused by aphis exudates and other agencies.

Dissociation Energy of the CO Molecule

In the last lines of my letter in Nature of June 29, p. 1077, I erroneously wrote $C(^1D) \rightarrow O(^3P)$ instead of $C(^3P) + O(^1D)$. This, together with a typographical error, obscured the meaning of the last sentence. It should read: "The alternative possibility that it would correspond to dissociation into $C(^3P) + O(^1D)$ and that therefore $D_{CO} = 9{\cdot}105$ v.e. will be discussed in detail elsewhere."

B. Rosen.

Institut d'Astrophysique,
Université de Liége,
Belgique.

Points from Foregoing Letters

Dr. R. Broom has discovered tooth germs in the lower jaw of a young specimen of the Platypus, which are considerably anterior to the teeth already known. They are believed to be two incisors and a canine. If this determination of the germs be correct, *Ornithorhynchus* would seem more probably to have been descended from an Ictidosaurian reptile or a Pantotherian mammal in which there are large canines, than from a Multituberculate in which the canines were early lost.

By bombarding fluorine compounds with alpha rays, Dr. O. R. Frisch has obtained a radioactive element of long life emitting positrons. It follows the reactions of sodium and is probably Na^{22}, though from the behaviour of Cl^{34}, P^{30} and Al^{26}, Na^{22} should have a short period. A radio-element of half-period 4·4 hours, probably Sc^{43}, has also been obtained by Dr. Frisch by the action of α-particles on calcium.

The rate at which carbohydrates are formed by plants from carbon dioxide and water in the presence of light depends, according to Dr. W. O. James, upon structural considerations which affect the amount of carbon dioxide reaching the chlorophyll granules; also, the energy absorbed from the light is greater than one quantum per reacting molecule. Hence the simplifying assumptions made in some of the formulæ put forward to explain the reaction appear unjustified.

Dr. M. Ritchie gives some explanations in answer to H. J. Schumacher's criticisms of his experiments on the rate of decomposition of ozone by heat ($O_3 \rightarrow O_2 + O$) and the deductions therefrom.

Prof. A. V. Hill directs attention to divergencies in the use of symbols representing various physical magnitudes, and appeals for greater consistency in the derivation of such symbols.

Prof. E. W. Scripture gives an example showing that, by analysing a curve according to Fourier's method, one does not necessarily obtain the true components. He supplies illustrations of sound-film tracks representing vowels, the outlines of which support the Willis-Helmholz-Hermann theory of a series of short free vibrations rather than Wheatstone's theory of overtone resonance.

Two new methods for measuring the mechanical stresses due to vibrations are described by Dr. A. Bloch. One is based upon the change in electrical resistance in a specially prepared carbon coating which is directly applied to the surface under examination, and the other upon electrical changes in a crystal of quartz or Rochelle salt cemented to the structure to be examined.

W. F. Floyd directs attention to an error in the analytical treatment of the graphical representation of complex numbers by Wessel in 1797, due to inconsistency of symbolism. The error, Mr. Floyd states, is still found in many textbooks.

Dr. W. Bleeker submits two photographs taken in Holland of a 'fire-ball' which, calculations show, fell in the North Sea near the coast of southern Scotland on March 24; it was not seen in the British Isles, owing to clouds.

Erratum. In the penultimate and last lines of the note in Nature of August 3, p. 187, on the communication by A. Emmerie, the phrase "constituents responsible for the Carr and Price reaction" should read "constituents which cause a reaction simulating the Carr and Price reaction".

Research Items

Further Investigations at Hoxne, Suffolk

FURTHER exploratory work at Hoxne was undertaken by Mr. J. Reid Moir in 1934 on behalf of the American School of Prehistoric Research (*Bull.*, 1935, No. 11). Excavations were made both on the old brickfield site and also on the recent extension of the area of exploration to Oakley Park. In both, the present investigation exposed a section showing the stratification which affords evidence of climatic change. An addition to the fauna of the brickfield area was (?) *Sus scrofa*, associated with Clacton III, and also with other mammalian remains which show no signs of a cold climate. The Oakley Park excavation opened up an impressive section, from which it was plainly evident that the uppermost and lowest deposits were laid down under intense glacial conditions, while the intervening beds were accumulated during a temperate period. These latter are, therefore, to be regarded as inter-glacial, and represent the epoch when Late Acheulian and Early Mousterian man inhabited East Anglia. The Late Acheulian and Early Mousterian floors are associated with seams of peat, of which samples have been sent to Dr. G. Erdtman, of Visby, Sweden. His report shows that the Early Mousterian floor was laid down in temperate conditions. Dr. Erdtman, however, states that the most interesting fact revealed by his preliminary analysis is the presence of *Abies*, which had not previously been reported in the Quaternary deposits of Britain. It represents a family which has living representatives in eastern North America, China and Japan, but in Europe is represented only by fossil species (Tertiary or earlier). *Picea* and one, or several, other species not previously found in European post-Tertiary deposits also appear. Dr. Erdtman suggests a measure of caution in immediate acceptance of this evidence at its face value.

Ear Exostoses

IN a study of ear exostoses by Dr. Aleš Hrdlička (*Smithsonian Misc. Collect.*, **93**, No. 6), it is pointed out that few subjects in racial pathology have received more attention than this. The term is here used to cover all bony excrescences or tumours within the external auditory canal, though these have received a number of names. The existing literature contains material of distinct anthropological value, though it is defective for certain areas, notably Africa, China, India and Malaya and less markedly the Pacific. Ear exostoses are relatively frequent among Polynesians; but taken as a whole, they are scarce among European and American whites, while among American Indians their frequency is marked. Dr. Hrdlička has not only reviewed existing records, but also has added the results of a personal examination of 7,814 skulls, forming part of the Division of Physical Anthropology, United States National Museum. From this material he concludes that the abnormality is one of considerable antiquity, going back about four thousand years to XIIth Dynasty Egypt. No example has yet been found in early man or even in neolithic times. Its frequency among American Indians, however, suggests a higher antiquity than that for which there is evidence at present. The tendency to ear exostoses is probably a pan-human condition, though there is considerable local variation. It does not occur among the anthropoids. The underlying process is probably not a degeneration, but a somewhat inadequate central control of the neuro-vascular system of the parts involved, with bony abnormalities as a secondary manifestation. It is suggested that in the rapid progress and differentiation which has accompanied man's astoundingly rapid evolution, the central trophic control of the external meatal region in the greatly enlarged, altered, and still altering skull has not regained the full life-long adequacy that it possessed before.

Intelligence Tests on Japanese

REPORT No. 25 of the Institute for Science of Labour, Kurasiki, Japan, is an account of a "General Intelligence Test and its Norm", by Dr. Hoken Kirihara. Four tests were used, namely, rote memory, recognition, completion and analogy, and Rybakow's figure tests. The problems were completely non-verbal, apart from the instructions, and it is hoped that they may serve as a basis for comparing racial differences in intelligence. The results from applying the tests to about 12,000 Japanese males and females, aged from 6 to 40 years, are given in this report, and certain occupational standards have been worked out. Correlating the mental ages of 230 boys and girls derived from this test with those derived from the Binet-Simon test gave a coefficient of $+ 0{\cdot}723 \pm 0{\cdot}0213$. It was found to be too difficult for children below the age of nine years. The rote memory sub-test was not reliable for children more than twelve years old. The results have shown the developmental growth of intelligence in the different phases of childhood, pre-pubescence and pubescence. The development of the female appears to be a year ahead of that of the male, to stop a year sooner, and to be corresponding up to the twelfth year, but throughout pubescence to be absolutely less than the male. This report outlines an extensive investigation.

Chinese Starling in America

ABOUT 1897 the crested myna or Chinese starling was set free in British Columbia, and although increase in numbers was slow, it became well established. By 1925 the Vancouver colony included more than 20,000 individuals, and wanderers had been found across the international boundary in Washington State (T. H. Scheffer and C. Cottam in *U.S. Dept. Agric. Tech. Bull.*, No. 467; 1935). Further distribution has been limited, partly because climatic conditions do not favour undue increase, and partly because physical barriers—mountains on the north, extensive forests in the interior, and ocean straits to west and south—check dispersal except in an easterly or south-easterly direction. The authors, having examined the food, state that the potentiality for harm of such a gregarious and omnivorous bird, which plays havoc with fruit, is high; and that consequently every precaution should be taken to check the spread of this species and to prevent its establishment in the United States. But with introductions this is often more easily planned than accomplished.

Reptiles and Amphibia of the Antilles

LESS than five years after the publication of his List of Antillean Reptiles and Amphibia, Thomas Barbour finds it necessary to compile a new one, so many additional discoveries having been made that the old list is completely out of date. The new list contains names of species and races, with, for each, a brief note upon locality or habitat (*Zoologica*, 19, No. 3, June 1935). The variety of life in these islands, which comprise the West Indian Islands, except Trinidad, Tobago and the islands off the coast of South and Central America, is astounding. Compare the 86 forms of Amphibia and 370 reptiles, the latter including 266 lizards, 98 snakes, 3 chelonians and 3 crocodiles, with the corresponding fauna of Britain as tabulated in the new Vertebrate List, 7 amphibia, 9 reptiles!

Pearl Organs in Fishes

DR. Y. OKADA notes the occurrence of bead-like organs or tubercles in certain Japanese cyprinoid fishes (Science Reports, Tokyo Bunrika Daigaku, Sect. B, No. 28; 1934), the so-called pearl organs. The occurrence of these organs is apparently well known in the nuptial males of cyprinoid fishes, and previous authors have indicated that these secondary sexual characters have some special purpose in the breeding season, possibly being used for preparing the surface of the rocks on which the eggs are laid. The pearl organs of the Japanese cyprinoid fishes develop mostly on the tip of the snout or on the side of the face, but are also often found on the fins, the ventral surface of the caudal peduncle and the posterior part of the body. The author suggests that the tubercles may serve as contact organs, holding the mating pair entangled by the roughened surfaces. The pattern and position of the organs are different in the various species and occur in *Cyprinus*, *Carassius*, *Tribolodon*, *Acheilognathus*, *Ischikauia*, *Zacco*, *Opsariichthys* and *Sarcocheilichthys*. These tubercles are so like the so-called sensory papillæ of the Gobiidæ, and the arrangement in some cases is so much the same, that there seems to be some relationship in these organs. The gobies also lay their eggs on rocks or shells, and possibly the organs have a similar function as suggested above in the clearing of surfaces preparatory to egg-laying.

Oyster Culture in Norway

A DETAILED account of oyster culture in Norway has been published by Torbjørn Gaarder and Paul Bjerkan ("Østers og østerskultur i Norge, utgitt med bidrag av Fiskeridirektoratet", Bergen, 1934). The first part of this work consists of a clear description of the anatomy of the north European oyster *Ostrea edulis* and its young, including its chemical composition, biology and the risks that it runs, including its enemies. The second part deals with oyster culture in general, and there is a special account, occupying more than half the work, on oyster culture in Norway. The natural oyster banks along the Norwegian coast are now almost empty and little used, but the natural pools more or less connected with the fjords are ideal for oyster culture. These are of two kinds, the almost closed pools for breeding and the open basins for rearing. The hydrographical conditions make them specially suitable; there is abundance of good food and they are sheltered from wind and waves. Although much has already been done, a great deal more is expected, and the present interesting paper shows what has already been accomplished and indicates the way to further progress. Good illustrations accompany the text, both photographs showing the types of pools and line drawings showing the oysters and gear.

Table-Poultry Production

THE Ministry of Agriculture and Fisheries has issued an account of experiments in table-poultry production carried out as part of the National Poultry Institute scheme begun in 1923 (Bulletin No. 91, H.M. Stationery Office. Pp. 59. 1*s*. net). The experiments dealt with the best methods of feeding and marketing table poultry and with the relative values of the breeds generally kept by commercial egg farmers. Feeding investigations showed that dry mash gave better results than wet mash (though not better than wet and dry combined) and had the further advantage of a saving in labour costs. Reduction in expenses could also be made, without reducing the bird's gain in weight or the quality of the flesh, by substituting barley meal and maize for Sussex ground oats, and by reducing the dried milk constituent by 50 per cent.

Downy Mildew of Millet

A DESCRIPTION of "Mycological and Pathological Studies on the Downy Mildew of Italian Millet" by Makoto Hiura has recently been published (*J. Fac. Agric., Hokkaido Imp. Univ.*, **36**, Part 2, March 1935). Symptoms of the disease on Italian millet (*Setaria italica*) are given in very great detail. Systemic infection from oospores in the soil produces large chlorotic spots on the leaves, which bear conidia. These either germinate directly, or produce zoospores, which bring about secondary infection and give limited yellow spots. Oospores are produced in the leaves and flowering spikes; the former are quickly shed from the plant, whilst the latter are much deformed. The causal fungus is *Sclerospora graminicola*, and the paper under review describes the size and mode of germination of the conidia, zoospores and oospores, the influence of atmospheric conditions upon their shedding and germination, the host range of the fungus, and various methods of infection. Control methods are not described, but it should not be difficult to evolve them from the detailed study here presented. Six excellent plates illustrate symptoms and characteristics of the fungus.

Irrigation of Market Garden Crops

THE practice of irrigating growing crops is very ancient, and was probably used in the Nile basin as soon as human beings commenced the art of growing plants in garden or farm. Many modern horticulturists use the water-can or hose-pipe in summer, but the provision of water for extensive outdoor crops is a new development in England. Mr. F. A. Secrett has published a very interesting paper on "Irrigation for Horticultural Market Crops" (*J. Roy. Hort. Soc.*, **60**, Part 7, July 1935), in which he describes an apparatus for irrigating four acres of ground at one time. A centrifugal pump of suitable capacity delivers water to a system of permanent mains laid on the farm. Valves are provided every 40 ft., and connexions may be made from these to the spraying lines, which are long pipes with nozzles 2 ft. apart. Water is thus made to descend upon the crop as a gentle rain. Provision is also made for aerating the water, and an ingenious arrangement

adds minute quantities of fertiliser at any predetermined rate. A crop must never be irrigated unless it shows signs of distress; heavy soil or poor ground lacking humus will not respond to the addition of extra water, and certain crops must only be watered at night. Many other practical points are given in the paper.

Refrigeration Hygrometry

THE scientific investigation of the conditions under which food of various kinds may best be kept for long periods, without deterioration in quality, has shown that for each food there is a best temperature, a best composition of the atmosphere surrounding it and a best moisture content of that atmosphere. The question of the standardisation of hygrometers for measuring the moisture content of the air in cold storage chambers has been examined at the request of the Food Investigation Board of the Department of Scientific and Industrial Research by Mr. J. H. Awbery and Dr. Ezer Griffiths, of the National Physical Laboratory, and the results of their work are published in the July issue of the *Proceedings of the Physical Society*. The indications of a wet- and dry-bulb hygrometer were compared with those of a special dew point instrument and of a gravimetric absorption apparatus, all enclosed in a large metal chamber the temperature of which could be maintained constant at 0° C. down to − 19° C., and the air within at any desired humidity. The results are embodied in a table of humidities in terms of dry-bulb temperatures 0° to − 19° C. and wet bulb depressions 0° to 4·2° C., which differs considerably at temperatures of the dry bulb below − 8° C. from those previously available.

A Novel Optical Gauge

AN interesting brochure on optical gauging and inspection has recently been published by Messrs. Adam Hilger, Ltd. In the course of the many years' experience of this firm in the manufacture of high-grade optical instruments, it is only natural that it should have developed optical methods for testing and inspection in the engineering section of its work. In addition to the various interferometric methods, required only for work of the highest precision in gauge-testing, the booklet describes a new tool termed the 'Angle Dekkor'. It consists of a sturdily made modification of the autocollimating telescope, by means of which a reflected scale image is observed at right angles to a fixed scale in the eyepiece, thus measuring the tilt of the reflector from the normal direction. The scale of the standard instrument has a range of 25′, on each side of zero, in the direction of the fixed scale, and the image scale measures a range of ± 20′ in the perpendicular direction. On both scales, each division corresponds to a tilt of one minute of arc, and a fifth of a division can be estimated without any difficulty. When the Angle Dekkor is used in conjunction with an accurate quartz or glass set-square, a pentagonal prism or a screw-pitch attachment, a very large variety of engineering gauges and other products can be quickly tested. For example, it affords a rapid means of checking the truth of the various motions in a universal milling machine and the relations of these motions to each other. The importance of this new tool lies in the fact that the order of magnitude of the errors it conveniently measures is that commonly met with in ordinary engineering practice.

Theory of the Ionosphere

H. G. BOOKER (*Proc. Roy. Soc.*, June 1) has published calculations of the behaviour of vertically propagated wireless waves in an ionised medium in which both the concentration of the ions and the chance of collision between them varies with height. The calculation is made first for the core in which the earth's magnetic field is neglected. A simple variation of ionic density and collision frequency is assumed and it is shown that waves below a certain frequency are not reflected. As the frequency is raised from the critical value the strength of the reflected wave rapidly increases, reflection taking place at progressively increasing height. Very long waves may be specularly reflected by a different mechanism. In the presence of the earth's field there are two characteristic waves for which the complex refractive indices are different. Two approximations are available corresponding roughly to propagation along and across the lines of force, and it is shown that these approximations cover a large number of the possible cases. For frequencies near the characteristic magneto-ionic frequency, the extraordinary wave is nearly suppressed. A region of absorption may exist below the deviating region, and the dependence of absorption on frequency for high frequencies is different according to whether the absorption takes place in this lower region or in the neighbourhood of the reflecting layer.

Yale Stellar Parallaxes

WE have received the second edition of Schlesinger's "General Catalogue of Stellar Parallaxes", published by the Yale University Observatory. The second edition contains all trigonometric, spectroscopic and dynamical parallaxes available through publication or correspondence in January 1935. The convenience of having such a catalogue is self-evident, and the practice of issuing editions as frequently as is financially practicable is obviously commendable. The main catalogue lists the star's name, R.A. and Dec. for 1900, magnitude and spectrum, parallax (both trigonometric and spectroscopic), the proper motion and the DM number. Dynamical parallaxes are found in a supplementary catalogue. Prof. Schlesinger is to be heartily congratulated on the appearance of the second edition of his Catalogue.

Greenwich Stellar Parallaxes

H.M. STATIONERY OFFICE has published the "Observations of Stellar Parallax", Vol. 2, from photographs taken and measured at the Royal Observatory, Greenwich, under the direction of Sir Frank Dyson. The Greenwich parallax programme is limited to stars north of declination + 64°, that is, to the Greenwich astrographic zone. The plates were exposed in the Thomson 26-in. photographic reflector, of focal length 22 ft. 6 in., and each star was photographed at five epochs, at least four plates being secured at each epoch. The probable error of the average parallax is estimated at 0·0085″. The publication of the present volume brings the total of Greenwich parallaxes to 516 of which Nos. 267–516 appear in the present volume. The largest parallax found so far is 0·247″, and there are 37 parallaxes which exceed 0·050″. The present volume presents tables showing the distribution of absolute magnitude with spectral type. Details of each photographic plate are given in the main table in the volume, and the parallaxes, relative to the comparison stars, are tabulated in a catalogue at the end of the volume.

Work of the Chemistry Research Board

THE report of the Chemistry Research Board* drawn up by the present director, Prof. G. T. Morgan, summarises the work carried out in the Government Chemical Research Laboratory during the first ten years of its existence, and is an impressive record of a large amount of valuable research in various fields. Much of the work has an industrial bearing, and there has been useful collaboration with several firms, members of the staffs of which have been attached to the laboratory. A list of more than a hundred published papers is given, together with particulars of some thirty patents.

The first part of the report deals with researches on the corrosion of metals, which have had reference to the mechanism of corrosion in its relation to the prevention of rusting, tarnishing and corrosion of metals in industrial use. An anodic oxidation process for aluminium, in which the metal is protected by an oxide film produced electrically, was worked out, and a means of colouring aluminium has been adopted in industry. The protection of magnesium and its alloys, which are used in the aircraft, motor-boat and automobile industries, against corrosion by sea-water and motor fuels, is being studied, as well as the corrosion of locomotive boiler tubes, zinc and purified iron and steels.

The report then deals with high-pressure investigations, including the synthetic production of alcohols from carbon monoxide and hydrogen, and acetic acid from carbon monoxide and ethyl alcohol. The starting point of these syntheses is represented by materials obtainable from coal. The equipment recently constructed is designed for work at 3,000 atm. at a temperature of 200° C.

New methods of carbonising coal have led to the production of tars which differ considerably from those familiar in industry. New methods of separation have made possible the identification and classification of the components of tars produced by various methods. Certain tars contain phenolic constituents readily separable by distillation, and these, in solution in caustic soda, form a very efficient and cheap wetting-out agent for use in the textile industry, which is now marketed under the name of 'shirlacrol'. The application of high-pressure technique to coal tars has produced new compounds which have been tested for possible use in the dye industry.

A large amount of work has been done on synthetic resins, and a tough transparent resin has been obtained which resembles glass and may find application as a material for artificial dentures. Experiments with the object of making synthetic resins direct from tar oils indicate the possibility of simultaneously separating the valuable hydrocarbon oils. Resins formed in this way have been used for impregnation purposes, as they prevent the growth of mildew.

Since 1931, work has been proceeding in co-operation with the British Road Tar Association for the improvement in the efficiency and quality of road tars. It has been found that light, as well as air, may be important in connexion with the life of tar applied to roads.

Several problems concerned with micro-organisms have been dealt with. A method of preparing acetone-alcohol mixtures, useful as liquid fuel and otherwise, from straws and waste vegetable matter by fermentation has been demonstrated, and other investigations in this branch include the effects of micro-organisms in the deterioration of fabrics and in tainting live fish in rivers, and the degumming of silk by lower fungi instead of acids.

The preparation and testing of synthetic drugs in co-operation with the Medical Research Council, the production of a base-exchange material for water-softening from British clays, the action of drinking water on lead, and investigations of the rarer metals are other branches of work described in the report.

* Department of Scientific and Industrial Research. Report of the Chemistry Research Board for the Period ended 31st December 1934; with Historical Introduction and Report by the Director of Chemical Research. Pp. v+94. (London: H.M. Stationery Office, 1935.) 1s. 6d. net.

Conifers of the Balipara Frontier Tract, Assam

IN the *Indian Forester* of May 1935 (61, No. 5, *Civil and Military Gazette* Press, Lahore), Dr. N. L. Bor, of the Indian Forest Service and at present political officer, writes on "The Conifers of the Balipara Frontier Tract, Assam". As a forest officer in Assam, Dr. Bor has taken full advantage of exceptional opportunities to study the forest flora of the more unknown parts of the country; some of his best work in the almost unknown region of which he is now in charge is briefly described in the article under review. The flora of this section of the Himalaya was practically unknown up to recent times and he set to work to collect, the considerable results of his activities being now under examination at the Royal Botanic Garden, Sibpur.

The area of the Eastern Himalaya in question covers an enormous tract of country exhibiting every variety of climate from that of the sweltering plains of Assam to the arctic climate of the eternal snows. Its northern boundary is the lofty Sela Range which sweeps north-eastward from the Tibet-Bhutan border and divides the Balipara Frontier Tract from Tibet proper. It contains a number of peaks more than 21,000 feet in height. Several travellers, Bailey and Moreshead, Kingdon Ward and others, have crossed the Sela pass into Tibet, but the southern slopes to the east are unexplored.

Dr. Bor gives details of the configuration of the region, its extraordinarily variable climate, its geological features and inhabitants. A study of the latter

would appear a sufficiently heavy task, for from west to east "are to be found Sherchokpas, Sherdukpen, Tembangias, Khoas, Akas, Mijis, Miri Akas, Daflas, Apa Tanangs and Miris, all differing in language, custom and dress. . . . The Western tribes are peaceful and well disposed to us. The Daflas and Apa Tanangs are, however, inclined to be truculent and it is impossible to tour in their country without an escort".

The conifers discussed in the paper are *Pinus excelsa*, *P. longifolia* (in extensive pure forests), *Abies delavayi*, in pure crops on the northern slopes of Piri, between 9,000 ft. and 10,727 ft.; its home is in Szechuan, China, this being a new record of its presence in Assam. Associated with it are species of *Rhododendron*, oak, etc.

Perhaps the most interesting of the investigations carried out are those recorded in connexion with *Pinus excelsa*. This conifer occurs in two places only —the Tenga valley in the west and the Apa Tanang country to the east, two localities which are some 150 miles apart. In the Tenga valley the climate is dry, and the tree flourishes at between 5,000 ft. and 9,000 ft. Regeneration of the *P. excelsa* is very satisfactory if protection from fire is afforded.

The most interesting information with reference to this species comes from the Apa Tanang country. Here the rainfall is much higher, the elevation being 6,000–7,000 ft. The tree reaches a great size, 150 ft. in height with a girth of 14 ft. The wood of *P. excelsa* is used largely by the Apa Tanangs as fuel and for building material.

The most striking feature of this valley is the fact that the pine grows pure on the inner slopes only of the bowl, and pine trees are not found beyond the lip. On all sides the evergreen forest is apparently encroaching upon the pine, and dead pine trees can be seen emerging high above the evergreen forest on the inner side of the lip. A meticulous search in the pure pine forest failed to reveal a single seedling, showing that the pine seed cannot germinate and develop in the present conditions. It seems as if the pine is a remnant of a very large area of pure pine which is slowly dying out. In any event, it is clear that the *Quercus-Michelia-Acer hylium* is advancing upon it and will eventually prevail. This view is confirmed by certain of the Apa Tanang's elders, who told Dr. Bor that the area under pine has decreased even within their time, and that their forefathers had come to the same conclusion as that outlined above, and had as a consequence with considerable foresight ordered the tree to be raised in plantations. Seed is broadcast on hoed ground and the area protected from fire.

In the Zhob country of the Baluchistan frontier, the Sheranis attach equal value to the *Pinus gerardiana* both for its seed and timber, and endeavour to protect these forests from fire. But Dr. Bor's account of an aboriginal tribe successfully raising plantations by the cheap measures recorded must be unique.

Broadcasting in India

THE growth of radio broadcasting during recent years has been so marked that in most of the larger European countries, in the United States of America, in Australia and in Canada, the number of registered listeners exceeds five per cent of the population. Actually, the number of licensed listeners in Great Britain and Northern Ireland at the end of 1934 amounted to about 15 per cent of the population. In India, however, with its population of more than 350 millions, the number of registered listeners is less than 12,000, or about 0·003 per cent. This fact, with many others illustrating the very elementary stage attained by radio broadcasting in India, is given in a paper by Mr. K. Sreenivasan entitled "Development of Nation-wide Radio Broadcasting in India", published in *Electrotechnics* for April 1935.

After reviewing the ideals and objects of a national broadcasting service in any country, Mr. Sreenivasan discusses the status of broadcasting in various parts of the world, illustrating the main facts with a useful table of statistical data. He then passes on to the consideration of a broadcasting scheme suitable for India to replace the three existing transmitting stations. The suggested scheme involves the installation of about five national transmitting stations and sixty regional stations, with an additional five short-wave transmitters for international long-distance broadcasting. The proposed distribution of these stations is illustrated by a map, and the scheme is considered to be adequate to serve all interests and requirements, having due regard to the various languages involved. In the matter of power allocation, each of the national transmitters would have 250 kw. in the antenna, the regional stations would vary between 25 kw. and 75 kw., while the short-wave stations would be of 50 kw. rating. This gives a total power of nearly 5,000 kw., or about one watt per square kilometre for India, as compared with the existing figure of about 2·3 watts per square kilometre for Great Britain.

With regard to the distribution of receivers, Mr. Sreenivasan considers that, owing to the low standard of living prevalent in India, particularly in rural districts, there is no satisfactory alternative to community ownership of receivers and community listening. Even so, it is estimated that some $3\frac{1}{2}$ million receivers will be required as an immediate objective.

The paper then proceeds to a consideration of the outline of an organisation of an autonomous public utility type for the provision, maintenance and operation of this national broadcasting service. It is suggested that a central broadcasting council should work under a Minister of Communications, and in co-operation with a number of provincial broadcasting commissions. Further sections are devoted to proposals for financing the project and to the policy underlying the programmes to be provided. In conclusion, the author modestly expresses the hope that his paper will help to create a correct perspective of the vast problem involved in the matter of broadcasting in India, and will provoke reasoned discussion on this national question.

Studies of Nematocysts

IN a work of 700 pages (Travaux de la Station Zoologique de Wimereux, 10 and 11. Paris: Laboratoire d'évolution des êtres organisés, 1934. 125 frs. each) Robert Weill describes the results of his detailed observations on the Cnidaria with special reference to their nematocysts. His investigations have been made largely on fresh material derived from 113 species of cœlenterates.

A short historical summary is followed by a careful description of a nematocyst—an ovoid capsule with a circular opening at the narrow end closed by an operculum, and here the wall of the capsule is continuous with the tube enclosed in the capsule; the basal part of the tube is generally wider and straight, the distal part narrow and spirally coiled, and both parts of the tube have on the inner surface numerous spines inserted in groups of three. The tube is discharged through the terminal aperture and the remains of the operculum are usually demonstrable; at the same time the refringency of the capsule is lost, for its contents have been expelled. The author describes the wide variations in size of the nematocysts, from 5μ in length in some Alcyonaria to 1·12 mm. in length in the siphonophore *Halistemma*.

Weill classifies the different types of nematocysts into those with closed tube, of which there are three kinds, and those in which the tube is open at its tip, of which fourteen kinds are recognised. He discusses the question of nerve supply to the nematocyst cell and concludes provisionally that a nervous connexion is unlikely. The author is very decided that the discharge of the tube is not by its unbending, like a spring, but by its devagination, for by retarding the process the stages of extroversion can be followed under the microscope. The tube is longer and wider after discharge—it may be doubled in length—hence its wall is elastic and in the undischarged nematocyst is in a state of disequilibrium. After discussing the mechanism of discharge, the author accepts the view of Iwanzoff (1896) that the discharge is due to swelling of the contents of the capsule. Discharge can be brought about only in presence of fluid which penetrates the capsule, but what determines the endosmosis is not yet known.

The author describes his observations on the development of nematocysts, and traces the migrations of the nematocyst cells, for example, in the Lucernaridæ, from their origin in thickened ectoderm at the edge of the subumbrella to the tentacular knobs. Fully formed nematocysts appear to remain functional indefinitely. About three hundred pages are devoted to a consideration of the taxonomic value of the cnidome, that is, the ensemble of the nematocysts presented by a particular species of cœlenterate. In discussing the Gymnoblastea, considered to be an artificial and heterogeneous group, Weill considers that *Hydra* represents not a primitive but one of the most complex genera, and should be placed near the Tubulariidæ. The study of the cnidome confirms the distinction between the Milleporidæ, which are allied to Gymnoblastea, and the Stylasteridæ, which are near the Calyptoblastea. Incidentally, the author does not accept Willey's observation that the filament of a discharged nematocyst of *Millepora* can be withdrawn or retracted. In their cnidome the Scyphozoa approximate more to the Hydrozoa than to the Anthozoa. Alcyonaria have a homogeneous cnidome different from that of Zoantharia. The bearing of the cnidome on the classification of anemones and corals is discussed.

This important monograph concludes with an extensive bibliography and an index of the genera and species referred to in the work.

British Association at Dublin in 1835

THE fifth meeting of the British Association was held at Dublin during the week beginning August 10, 1835. The president was Dr. Bartholomew Lloyd (1772–1837), provost of Trinity College, Dublin, the vice-presidents, Lord Oxonantown and the Rev. William Whewell, while the local secretaries were William Rowan Hamilton (1805–1865), Astronomer Royal of Ireland, and Humphrey Lloyd (1800–1881), Erasmus Smith professor of natural and experimental philosophy. The scientific proceedings were dealt with in six sections: (I) Mathematics and Physics; (II) Chemistry and Mineralogy; (III) Geology and Geography; (IV) Zoology and Botany; (V) Anatomy and Medicine; and (VI) Statistics, to which was added during the meeting the subsection on Mechanical Science Applied to the Arts. The meeting was largely attended, and there was a great deal of entertaining. Among the most famous men of science who were present were Sedgwick, Ross, Franklin, Agassiz, Dalton, Lardner, Babbage, Murchison, Rennie, Sabine, Wheatstone, Scott Russell and Eaton Hodgkinson. During the meeting the University conferred degrees upon William Smith, Sir Thomas Brisbane, Francis Baily, Prof. Moll and M. Agassiz.

Official reports of the proceedings were communicated to the editors of the *Philosophical Magazine*, and the daily papers gave accounts of some of the meetings. Perhaps the liveliest reports of the meeting were those published in the *Athenæum* of August 15, 1835, and succeeding issues, and from these a few extracts have been taken. The first portion of the report said: "The British Association has received, as we anticipated, a great accession to its members in Dublin, though many who intended to join it have been detained by their Parliamentary duties and by the Assizes. Still so many candidates presented themselves that the local council was compelled to place some restrictions on admission and to refuse, unless under special circumstances, all

applications made after Wednesday, the 5th of August, by persons residing in Dublin. . . . The arrangements made by the reception committee were excellent. . . . Accommodations were provided for a great number of guests within the walls of the College, and arrangements made for their breakfasting and dining together in the College Hall, by which the intercourse between the members has been greatly facilitated. . . ."

On Saturday, August 8, the Examination Hall of Trinity College was crowded. "Sir John Ross, Sir John Franklin, Dr. Coulter, the recent explorer of Mexico, Dr. Dalton, Dr. Roget, Professors Babbage, Powell, Murchison and many other eminent men, were among the crowd, evidently enduring some inconvenience, that they might gratify the curiosity they had excited. . . . In the list of names of members admitted on Saturday were to be found men of every creed, sect and party—Protestant clergymen, Catholic priests, and dissenting ministers—all anxious to gain a respite from agitating controversies, and enjoy a week's repose on the neutral ground of science. Visitors streamed into Dublin by the packet boats on Monday morning but by about eleven o'clock the whole of the Sections were in working order. The General Meeting of the Association took place in the Rotunda where Dr. Lloyd delivered his address and Prof. Hamilton read a report. The last function was a farewell dinner given by the Provost and Fellows of Trinity College to the Lord Lieutenant, Lord Musgrave, and 300 of the members of the Association. Just before the dinner Lord Musgrave conferred a knighthood on Hamilton, remarking in his speech, 'This is an exercise of one of those prerogatives of royalty, of which I am here the representative, most grateful to myself—most in unison I feel assured with the wishes of that august sovereign on whose behalf I act. . . . This act does not so much confer distinction, as place the royal, and therefore national, stamp upon that distinction, which has been acquired by personal qualifications and individual executions.' . . ."

In his summing up of the meeting, the correspondent of the *Athenaeum* wrote: "The meeting of the Association is now over and before we proceed to draw up a record of its proceedings we must say a few words on the general results of the week, and the impression left on our minds. On former occasions hospitality has been shown by the residents of the place of the assemblage to the way-faring visitors, and the business has preserved the 'even tenor of its way'; but in Dublin, notwithstanding the unusual quantity and quality of the scientific communications, business has been positively perplexed by the joyousness and festivities of the occasion. . . . Setting aside the distraction of mind incidental to the crowding together so much business . . . the vast number of all classes and pretensions who have joined the Association, and flocked to its halls, cannot have but disturbed the march of the proceedings. Imagine the Rotunda—a room capable of accommodating from 1,500 to 2,000 individuals—thronged to excess on some of the hottest evenings of this hot and cometary season: the ladies flirting and fanning; the gentlemen casting one eye upon Science and another upon Beauty; and the whole (saving the reader's presence) mopping and puffing and ready to drop with exhaustion and fatigue. . . . Even in the Sections themselves, the scientific men were not left in peace; both sexes were eager to attend them; and the ladies, as they could not be in the whole at once, made the best of their case by crowding in shoals to that particular section where the business was of the most abstract and recondite character. . . . The admission of ladies at the Sectional meetings, in direct opposition to the standing rule of the Association, is so manifestly calculated to destroy the efficiency of the Society, that we trust that there will be no repetition of this impropriety".

The treasurer of the Association in his report said that the receipts of the preceding year in Edinburgh were £1,626, while in Dublin they amounted to £1,750. It was very gratifying to be able to state that grants for the advancement of science of £1,700 had been placed at the disposal of the committee in 1835.

Educational Topics and Events

CAMBRIDGE.—F. R. Parrington, of Sidney Sussex College, has been appointed University demonstrator in zoology, and Dr. R. Knox and Dr. G. P. McCullagh have been appointed University demonstrators in pathology.

The Marmaduke Shield Scholarship for 1935 has been awarded to G. W. Harris, of Emmanuel College.

The offer of the Rev. J. H. T. Perkins, to give to the University a sum for the establishment of a Michael Perkins Fund, the interest of which is to be employed in making grants to young graduates working upon the natural history of animals, has been gratefully accepted.

DR. MARGARET S. SMITH has been appointed lecturer in agricultural chemistry and physics at the Horticultural College, Swanley, Kent, and will take up her duties in September.

THE University of Durham Act, 1935, which has now received the Royal Assent, sets up the following body as the University of Durham Commissioners for making Statutes for the University and its constituent divisions and colleges: The Rev. F. H. Dudden (chairman); Countess Grey; Sir W. Ross Barker; Prof. J. H. Priestley; Mr. C. Williams; Dr. G. R. Murray; Dr. T. F. Sibly; and Dr. A. Wood. Mr. A. C. Dawes will act as Secretary to the Commissioners.

THE New South Wales Ministry of Public Instruction in its last annual report gives information on the progress of its system of correspondence teaching, a system which some authorities in America would adopt in certain sparsely populated areas. The average enrolment of pupils taught by correspondence was 5,300 in primary and 210 in secondary grades, and the system, begun fifteen years ago, is reported to be still meeting with marked success. The provision of secondary education up to the intermediate standard was a new development, the outlook of which is promising. In each section of the primary department a special class of backward pupils receive special treatment. A weekly half-hour broadcast from the correspondence school is a feature said to be much appreciated and is used for answering questions. Associated with the system are voluntary donations by the pupils, amounting up to date to more than a thousand pounds, towards certain charities for the benefit of children.

Societies and Academies

PARIS

Academy of Sciences, June 24 (*C.R.*, 200, 2129–2250). ALFRED LACROIX: The tectites of Indo-China without figured forms. These are not large drops of glass shaped by fusion in the course of their fall, but the debris of larger blocks, probably fractured by shock on striking the ground. GEORGES URBAIN, PIERRE WEISS and FÉLIX TROMBE: A new ferromagnetic metal, gadolinium. The specimen of gadolinium used was pure except for 0·7 per cent of silicon and 0·03 per cent of iron. This metal is ferromagnetic. The absolute saturation reached 253·5 C.G.S. units, that of iron being 221·7. The Curie point is 16° C. LUCIEN CAYEUX: The constitution of the Senonian phosphates of Egypt. JEAN BAPTISTE SENDERENS: The catalytic decomposition of the monobromo derivatives of fatty hydrocarbons. The alkyl bromides behave similarly to the chlorides, except that the temperatures required are higher. GEORGES DURAND-VIEL was elected a member of the Section of Geography and Navigation, in succession to the late Ernest Fournier. A. KULAKOFF: Some theorems connected with Burnside's problem. ANTONIO MONTEIRO: A class of Fredholm nuclei developable in series of the principal nuclei. HENRI MINEUR: The absolute magnitude of *B* stars with emission lines. The results of the analysis show that these stars do not differ from the ordinary *B* stars from the point of view of their absolute brightness, the emission arising from the large extension of their atmospheres. MARC DE HEMPTINNE and JEAN SAVARD: The ionisation potential of the nitrogen molecule. The method of electronic shocks has been utilised and the apparatus calibrated with argon and mercury. The energy of dissociation of the molecule N_2 calculated from the results, 6·72 volts, is in good agreement with the 6·8 volts deduced by Henry by another method. NICOLAS STOYKO and RAYMOND JOUAUST: The velocity of propagation of short radio-electric waves. FRANÇOIS CROZE: The general formulæ of refraction of a light pencil. YEU KI-HENG and YEOU TA: A new method for studying the corrosion of aluminium by soda. The metal is attacked by dilute soda solution in the presence of sodium tartrate, and the reaction followed by measurements of the rotatory power. A higher accuracy can be obtained by following the rotation than by the usual loss of weight method. M. MAHMOUD GHALI: A method for measuring the velocity of fall of spheres in a viscous liquid. A photo-electric cell in conjunction with an electrical recording apparatus is used: the time can be measured to 0·001 second. ANDRÉ PIGNOT and HUBERT GAUDRY: The useful surface of the membranes of pressure regulators. LÉON ARTSIMOVITCH, IGOR KOURTSCHATOV, LÉON MICCOVSKII and PIERRE PALIBIN: Concerning the capture of slow neutrons by a nucleus. IGOR KOURTSCHATOV, LÉON NEMENOW and IVAN SELINOW: The artificial radioactivity of ruthenium bombarded by neutrons. R. GRÉGOIRE: Bragg's curve of the H-rays. A. PERRET and R. PERROT: The cryoscopy of mixtures of nitrogen peroxide and bromine. No evidence could be obtained for the existence of the compound NO_2Br. MARCUS BRUTZCUS: A method for calculating *a priori* the calorific power of a technical combustible. The method is based on the quantity of oxygen required for complete combustion. A. MICHEL and GEORGES CHAUDRON: The influence of magnetisation at a high temperature and of crystallisation on the form of thermomagnetic curves. TCHENG DA-TCHANG and LI HOUONG: The precipitation of titanium as phosphate. Determination of the correct acidity for complete precipitation of titanium as phosphate. CLÉMENT DUVAL: A new method for studying complex compounds. A modified method for the study of the migration of ions under the action of an electric field can be applied to the examination of various complex compounds. Examples of the results obtained are given. EDMOND GRILLOT: Lead acetobromide. L. DOMANGE: The action of steam on some metallic fluorides. The results of experiments with the fluorides of silver, zinc and lead are given. PAUL BRASSEUR: Study of ferric orthophosphate. Description of the preparation and properties of anhydrous $FePO_4$. HENRI MOUREU and CLÉMENT HAMBLET: The mechanism of the reaction between liquid ammonia and tantalum pentachloride. The experiments show that in $TaCl_5$ two of the atoms of chlorine are more readily removed than the remaining three. PIERRE TRUNEL: The electric moments of isobutyl, isopropyl and phenyl chlorosulphites. G. DARZENS and ANDRÉ LÉVY: A new method of synthesis of derivatives of hydrophenanthrene and phenanthrenic hydrocarbons. MARCEL GODCHOT and MAX MOUSSERON: Some derivatives of 1,methyl.2,cyclopentanone and of 1,methyl.2,cyclopentanol. GEORGES BRUHAT and LOUIS WEIL: The measurement of the rotation of the plane of polarisation in oblique crystalline refraction. ANTONIN LANQUINE: New tectonic and stratigraphical observations on the zone of folding of Aups (Var). ANDRÉ DEMAY: The alternating or simultaneous action of magmatic and dynamic phenomena in the northern Cevennes. LOUIS DANGEARD and CHARLES BATARD: The conglomerates interposed in the Brioverian schists, to the north of the Coëvrons (Mayenne and Sarthe), and the nature of the cadomian movements. GILBERT MATHIEU: The tertiary faults of Vendée. MARCEL GESLIN: The influence of a current of warm water on the air and radon dissolved in a cold water. V. FROLOW: The annual component (pluviometry and hydrometry in the Argentine). ALEXANDRE DAUVILLIER: Study of the terrestrial field, of the atmospheric ionisation and of the vertical current at Scoresby Sound during the polar year. MLLE. MADELEINE FRIANT: The jugal dental type of *Pteromys xanthipes*. MLLE. MADELEINE FOURCROY: Modifications of the insertions of the rootlets in wounded roots. PIERRE POTEL and RAYMOND CHAMINADE: The oxido-reduction potential of flours. SERGE TCHAKOTINE: Physiological researches on the Protozoa made by means of the ultra-violet micropuncture. JEAN RIPERT and OLIVIER GAUDIN: The relative toxicity of pyrethrines I and II. ETIENNE WOLFF and ALBERT GINGLINGER: The characters of the intermediate sexual forms obtained experimentally in the embryo of the fowl. PAUL CRISTOL, RAYMOND SEIGNEURIN and JEAN FOURCADE: The absence of dissociation of thiourea and substituted thioureas in dilute aqueous solution.

AMSTERDAM

Royal Academy (*Proc.*, 38, No. 6, June 1935). W. H. KEESOM, J. MAZUR and J. J. MEIHUIZEN: The vapour pressures of solid krypton. Measurements between 78° and 116° K. and their comparison with the theoretical formula. W. H. KEESOM and

C. J. MATTHIJS: Measurements on thermoelectric forces from 17·5° down to 2·5° K. Extension of previous work to other alloys and lower temperatures. W. H. KEESOM and C. W. CLARK: The heat capacity of potassium chloride from 2·3° to 17° K. Measurements for the purpose of testing whether the rapid fall of the θ values for silver at lowest temperatures is due to the heat capacity of the conduction electrons. H. R. KRUYT and TRUUS KRUYT: Investigation on positive and negative carbon surfaces by adsorption of thorium B. The results indicate that OH ions form the surface of positive carbon and COOH that of negative carbon. E. DUBOIS: On the gibbon-like appearance of *Pithecanthropus erectus*. While possessing many gibbon-like characteristics, *Pithecanthropus erectus* fills the previously vacant place between the *Anthropomorphae* and man as regards cephalic coefficient. J. WOUDA: A new type of colorimeter. An apparatus which determines the re-emission of a coloured surface and automatically calculates the colour point. J. F. SCHOUTEN: Foundations of a quantitative four-colour theory (1). H. BULTHUIS: The spectrum of CO^+. Rotational analysis and perturbations of the $^2\Pi \rightarrow {}^2\Sigma$ bands. C. VISSER: On the angular derivative of univalent functions (2). C. S. MEYER: Integral representation of Lommel and Struve functions (1). W. VAN TONGEREN: Chemical analysis of rocks from Pulu Berhala. Analyses of the rocks described in the next paper. J. DRUIF: On rocks from Pulu Berhala (Malakka Strait). J. OUDMAN: Food reception and transport by the leaves of *Drosera capensis*, L. The growing leaves of this insectivorous plant do not form albumen from their food. IDA LUYTEN: The periodic development of *Iris reticulata*. J. B. THOMAS: The regulation of the breathing of *Lumbricus*. Oxygen consumption of worms in atmospheres of diminishing oxygen concentration was determined for normal specimens and for worms the hæmoglobin of which had been destroyed by carbon monoxide. H. DE JONG and A. GALLINEK: On surgical catatonia. The position of the surgical brain lesions which lead to catatonia in cats was determined.

BRUSSELS

Royal Academy (*Bull. Classe Sci.*, 21, No. 6, June 1935). L. GODEAUX: An observation on the rational correspondences between two algebraic surfaces. J. E. VERSCHAFFELT: The relation between the coefficients of the Ettingshausen and Nernst transverse magnetic effects. A discussion of papers of the same title by Mlle. Dupont. E. DE WILDEMAN: Adventitious buds in *Hæmanthus*. P. MORTIER: Molecular polarisation and association of ethyl alcohol in various solvents. Measurements of the dielectric constant of solutions of ethyl alcohol in benzene, carbon tetrachloride, hexane, heptane and carbon disulphide. L. MARTON: Electronic microscopy of biological objects. Description of apparatus. M. H. WUYTS and MLLE. A. LACOURT: The constitution of the thiohydrazides. These compounds can be methylated both at the α or β nitrogen atom and at the sulphur atom. A. DE WAELE: Researches on the migrations of the Cestodes (5). Study of the infection of the definite host by the hydatic larva. M. and R. BOUILLENNE: The soluble sugars in *Mercurialis Perennis*, L., (2). Nature of the soluble sugars and their respective amounts in the two sexes. P. DUSTIN: Note on the comparative histology of the splenic arterial coatings. Histological experiments to determine the function of the arterial coatings. F. CORIN: Discovery of a spilitic series and of pillow-lavas in Hesbaye.

MELBOURNE

Royal Society of Victoria, June 13. HELEN T. PATERSON: Notes on plant remains from Narracan and Darlimurla, South Gippsland. EDWIN SHERBON HILLS: A noteworthy specimen of *Spaniodon elongatus*, Pictet, from the Upper Cretaceous of Mount Lebanon, Syria. The specimen described shows the caudal half of a small fish (? *Spaniodon* fry) lying in the abdomen of a large individual of *Spaniodon elongatus*. It is argued that the small fish was swallowed by the large, and when fossilised, was lying with its anterior parts digested, in the stomach of the *Spaniodon*. The contents of part of the intestinal tube of the latter are also fossilised, and it is thought that this tube must have been relatively small and straight. The feeding habits of *Spaniodon*, as indicated by this specimen and by its large teeth, are considered to be incompatible with its taxonomic position in the *Engraulinae*.

VIENNA

Academy of Sciences, May 16. JOVAN JURIŠIĆ: Contribution to the knowledge of *Bryophyllum tubiflorum*, Harvey. WOLF JOHANNES MÜLLER and O. HERING: Theory of passivity phenomena (27). Time phenomena in anodic polarisation at smooth platinum in 2*N* sulphuric acid. In this polarisation, the pore surfaces first become coated with oxide, oxygen being evolved only at a subsequent stage. GEORG KOLLER and WALTER MAASS: A component of *Baeomyces roseus*, Pers. A lichen acid, $C_{19}H_{18}O_8$, is described. ALEXANDER KÖHLER: Optical investigations on synthetic mixed members of the felspar group. FRITZ KERNER-MARILAUN: Studies on the winter temperatures in alpine zone seas of the Keuper period. ARMIN DADIEU and HANS KOPPER: Raman spectra of HSD and ND_3. The Raman spectrum of HSD consists of two lines of frequencies 1880 and 2585 cm.$^{-1}$, which correspond with those of the spectra of D_2S and H_2S respectively. The spectrum of ND_3 consists of four lines of frequencies 2341, 2399, 2500 and 1588 cm.$^{-1}$, the relative intensities being 5, 5, 3 and 0 (?). ARMIN DADIEU and WOLF ENGLER: Raman spectra of SeH_2, SeD_2 and SeDH. The spectra of SeH_2 and SeD_2 consist each of a single strong line, the frequencies being 2312 and 1665 cm.$^{-1}$ respectively. These compounds should yield at least two Raman-active frequencies, the appearance of only one being explained by a valency angle of about 90°. The two lines of the spectrum of SeDH have the frequencies 2313 and 1671 cm.$^{-1}$. KARL MAYR: The position of the first positive null points of Bessel's functions of the first type. ROBERT WILLHEIM and CHARLOTTE FRISCH: Chemistry of crab glycolysis (1). Boiled crab juice contains factors which exert a reducing action, so that they disturb oxidative reactions. OTTO KOLLER: Note on a zoological research expedition to the mountains of north-western Asia Minor. ODOMAR GUGENBERGER: Stratigraphical position of the cephalopod fauna of the Casale Mountains, Palermo. EMIL ABEL and L. BLUMENKRANZ: Oxidation of oxalic acid by iodic acid when the stationary condition of the intermediate product is disturbed. ALEXANDER ROLLETT, NIKOLAUS KUNZELMANN and MAGDA BALOG: Investigations on azo dyes.

Forthcoming Events

[*Meetings marked with an asterisk are open to the public.*]

Sunday, August 11

BRITISH MUSEUM (NATURAL HISTORY), at 3 and 4.30.—Dr. J. Smart: "Insects".*

NATIONAL RADIO EXHIBITION, at Olympia, August 14–24.

Organisation of Industry

THE object of industry is to make commodities for the people : one reason for organising industry is to make more commodities at a lower price so as to raise the standard of living. This is the primary purpose for which industry exists, though necessarily every firm must carry out its operations at a profit, otherwise it cannot continue to operate when its resources have been expended. The profit is claimed by capital as a reward for the risks incidental to participating in business : if there were no such reward, there would be no incentive to invest in other than gilt-edged securities. Wages and salaries are paid as part of the cost of production ; they do not depend directly on profits, though in bad times the weekly wage-earner suffers lack of employment. A large school of modern thought seeks to make labour a more active partner in every manufacturing enterprise and would limit the reward to capital. In theory the idea is excellent, and where profits are good and more or less regular so that new capital is easy to obtain, its introduction into actual practice is attended with success. There are, however, industries and enterprises which are liable to fluctuations and therefore contain a considerable element of risk. These are difficult to finance, provide precarious employment and often no dividends ; in them the risks and the misfortunes have to be borne by capital and labour alike ; there is hardship to both.

When such industries are of the magnitude of the iron and steel or the cotton industry, the hardship is widespread, whilst the numbers of the workless or partially employed or lowly paid give them a political influence to express their grievances which tends to obscure the real nature of the problem and the steps which must be taken to solve it, always regarding the problem from a scientific angle as influenced by, and depending for its solution on, ascertainable facts and circumstances.

It is to the credit of the present Government that much of the real revival which has taken place in industry is based on the removal of difficulties of one kind and another by sound and non-political methods, sometimes by means of tariff protection or by other form of Government assistance, at other times by financial assistance in the form of refinancing with cheap money.

The need for industrial reorganisation to meet the changing problems of the day is an obvious one. Various schemes for doing this have been put forward ; some of them are of a drastic character, among which may be included those involving nationalisation.

It must be realised, though the fact is not always stated, that the ultimate prosperity of any particular firm depends on the individuals who manage it, and though they cannot rise superior to the bigger economic difficulties caused by world happenings, they can do much to mitigate the incidence of these. Too much importance may be attached to machinery and too little to leadership.

If it be granted that national prosperity depends on the level of industry, then to maintain this at a high level requires the elimination of the upsets caused by alternate booms and depressions. It is agreed that these ought to be preventable and that industry requires organising with this end in view. Whilst fair competition within an industry is essential, it should be possible in certain circumstances for an industry to act as a whole, either in relation to other home industries or when negotiating with the competitive industry in foreign countries. The subjects which concern an industry as a whole are numerous ; they

include research, propaganda, co-operative selling and buying, the collection of information and statistics, relations with labour, training, and more particularly the relations with our own Government in its many branches.

Such combination is effected by trade associations which, as experience is gained, are becoming more efficient, more comprehensive, more powerful and of greater use to their members and to the State. They have been developed alongside the changing conditions in industry. It is impossible to anticipate the changes or to provide for them, for they follow no rules: the more alert industries, which incidentally are those which are most scientific, are able to organise the most closely in point of time to the altered conditions.

It is essential that such organisations are entirely free from political partisanship and based only on strict economic considerations, and the same applies to the central organisation, the Federation of British Industries, which embraces all the separate trade associations as well as individual firms in its membership. Primarily formed to deal with questions of common interest presented by various Government departments during and after the War, the sphere of influence and utility of the Federation continues to increase, and it presents an organisation in advance of anything existing abroad.

Trade associations are purely voluntary, both in regard to membership and the decisions taken as the result of a majority vote. Recently the question has been widely ventilated, partly on the initiative of Lord Melchett, as to whether compulsory powers should be given to them through Order in Council, on the supposition that a full measure of industrial co-operation cannot be obtained through voluntary effort.

The compulsion of minorities is a principle which is so largely alien to British ideas that considerable attention has been given to the Bill introduced by Lord Melchett in the House of Lords. An influential committee was appointed by the Federation of British Industries to ascertain the views of trade associations and report the considered opinion of collective industry: this has been largely used in compiling the publication before us.* On this particular point it is stated by the F.B.I. Committee that the procedure of putting into force by Order in Council the decisions of the majority of an industry, when approved by an appointed tribunal and by the President of the Board of Trade, would be an undesirable addition to bureaucratic powers.

It is essential that Parliament should appreciate as it has generally failed to do in the past, that our whole national structure is dependent on industry, and that it must assist industry to maintain its efficiency. At bottom, industry must be financially sound, working at a profit, well and scientifically managed; redundancy, overlapping and waste must be eliminated. Though it would be tempting to have powers within an industry to force the scrapping of certain plant or prevent the extension of another factory where sufficient manufacturing capacity already existed, it is widely felt that the undue extension of compulsory methods would endanger the freedom of thought and action which we enjoy to-day.

Generally speaking, voluntary methods are proving successful; and although progress by such means is often slow, it can be speeded up very rapidly and without formalities when action is agreed. Compulsion by a majority introduces the effect of rigidity and would have a cramping effect on leadership. Indeed minorities, when progressive, are often in advance of general opinion and responsible for the new inventions and methods which bring prosperity.

There have been, of course, instances in which the failure of a trade to agree has brought increasing distress to workers and shareholders alike. The F.B.I. Committee, whilst emphasising their rarity, admits the necessity of dealing with these from without, and suggests a procedure involving examination by a tribunal appointed by the president of the Board of Trade. Lord Melchett, in favouring the appointment of such statutory committees, cites the success of the Tariff Advisory Committee and considers they would enable highly specialised industrial and technical problems to be dealt with by impartial and experienced individuals.

The Report, the consideration given to the question by the individual trade associations, the addresses given by Lord Melchett to various bodies, and those given by others who take an opposite view, have served to focus attention not only on what is a relatively minor point of compulsion versus voluntary co-operation, but also on the need for organisation within an industry. The importance and the value of co-operative effort have been emphasised in no uncertain manner, and the realisation that the firms in each and every industry must act nationally for the

* Survey of Britain's Recent Commercial Policy. Pp. 50. (Federation of British Industries, 21 Tothill Street, London, S.W.1.) 1s.

good of all rather than individually for the profit of the moment is proceeding apace. Instances multiply where several firms co-operate to make a new product instead of each setting up individually in competition; there is evidence that British industry is solving the new problems of the day: hence perhaps our trade revival, our recovery of such export markets as exist in spite of exchange and similar restrictions. It remains as the next step to carry this spirit of co-operation out into the Empire, to build on the foundations of amity laid at Ottawa.

Science and Philosophy

The Frontiers of Psychology

By William McDougall. (The Contemporary Library of Psychology.) Pp. xii+235. (London: Nisbet and Co., Ltd.; Cambridge: At the University Press, 1934.) 5*s*. net.

THE need for re-examining and redefining the boundaries of these two fields of intellectual activity has been felt more and more in recent years, and may be said to have become acute with Sir James Jeans's presidential address at the Aberdeen meeting of the British Association. The incursion of the physicist into metaphysics is a new and, to the psychologist no less than the philosopher, a most striking phenomenon. Time was, not so long ago, when the right of the psychologist to be regarded as a scientific worker was challenged on the ground that his pretended science was not science at all, but metaphysics, and no one challenged more loudly or more insistently than the physicist. There is doubt whether some physicists would concede the claims of the psychologist even yet, but it is certain that they must now formulate their challenge in different terms.

Prof. W. McDougall's little book is certainly well-timed in view of the metaphysical tendencies of the new physics. Possibly the author shows a tendency to exaggerate the importance of the position of psychology. After all, psychology is a very young science. He cannot be said to exaggerate the importance of including in our scientific account of the 'mysterious universe' phenomena which fall within the field of study of the psychologist, and his deprecation of the gap that has been created between the world of the new physics and the world as experienced is at least thought-provoking. The tone of the book is controversial—at some points pugnaciously so. Possibly also the author makes rather too much of inconsistencies in the writings of well-known physicists, which are due as much to the inadequacies of our language as to the doctrines of the new physics. None the less, the book is one which required to be written, and the author has presented clearly and cogently a case that required to be presented.

Among the many interesting problems on the frontiers of psychology with which McDougall deals there are two of fundamental importance. One is the relation between science and philosophy; the other, which is really involved in the first, is the place of the conception of causality in a scientific universe of discourse.

With regard to the first of these problems, it is very doubtful whether either scientific worker or philosopher would accept McDougall's solution. According to his view, science deals with facts, philosophy with values; science aims at knowledge, philosophy at wisdom. Truth has therefore a different meaning, and the criteria of truth are different for man of science and for philosopher respectively. For the man of science, a statement or proposition is true when it corresponds to facts, and the criterion of truth is the pragmatic one, that our anticipations based on the statement should be fulfilled. The pragmatic criterion, however, has no meaning for the philosopher. As concerned with values, he seeks validity rather than truth in the scientific worker's sense.

It is true that the points of view of science and philosophy are different, and when this difference is neglected, science may become a day-dream and philosophy a nightmare. Some scientific workers of the present day—McDougall cites Needham, but there are others—seem prepared to accept the view that modern science is a figment of the mind, representing the world of concrete reality as little as a day-dream. McDougall contends, and it seems to us rightly, that such a view of science, physical or biological, is untenable, since it involves the negation of the essential principle of science itself. The philosopher, however, is scarcely likely to accept McDougall's restriction of his sphere of influence to the realm of values. On such a view, logic, ethics and æsthetics would be included in philosophy, but metaphysics would be excluded. The philosopher seeks rationality in the world of fact as well as validity in the world of value. McDougall has apparently presented us with a view of science that might satisfy the philosopher, but would not

satisfy the man of science, and a view of philosophy that might satisfy the man of science, but would not satisfy the philosopher.

The problem of the place of the conception of causality in a scientific universe of discourse is clearly one aspect of the larger problem. The notion of causality is derived from the human being's experience of his own activity and its results. McDougall argues in effect that the scientific worker's distrust of anthropomorphism has led him to an impossibly extreme rejection of anything in the nature of agency, force, power, as concepts which may be legitimately employed in the scientific description of natural phenomena. He points out that science began in the search for causes in the naïve sense of the word, and that the search for causes is still in a very real sense the life-blood of science.

If such words as truth and causality are to have different connotations in science and philosophy respectively, it can only be regarded as a grave misfortune, and McDougall's plea for reconsideration from a psychological point of view merits at least a sympathetic hearing. After all, science and philosophy are both attempts to give a consistent and rational account of human experience. The hypostatising of abstractions, with which McDougall charges physicists, has as little justification as anthropomorphism, and less than a limited and reasonable anthropomorphism. Human experience itself is a fact of the universe which any comprehensive scientific description of the universe must include.

Other fundamental problems discussed by McDougall, such as progress and value, raise the same difficulties as regards the divergence and inconsistency of scientific and philosophical points of view. One may not always agree with McDougall's conclusions, but the value of the service he has rendered in the formulation of questions of pressing urgency for both science and philosophy can scarcely be denied.

Mathematical Methods in Meteorology

Physical and Dynamical Meteorology

By Prof. David Brunt. Pp. xxii+411. (Cambridge: At the University Press, 1934.) 25*s*. net.

PROF. BRUNT'S book covers the field that links meteorology with physics. The treatment is mathematical wherever tractable problems can be defined, and elsewhere more descriptive. As a whole, the book gives an impressive review of the growing success of mathematical methods within such an empirical science as meteorology. Much of this progress is of a rather recent date and a considerable portion of it is due to the efforts of British investigators, so that it is very much to be welcomed that one of these pioneers has now found the opportunity to present the whole field of physical and dynamical meteorology in text-book form.

Let it be said at once that the book is an admirable piece of work, well arranged, sound and clear. The chapters on thermodynamics and on turbulence deserve to be mentioned especially in this connexion. They are also more complete than has hitherto been the case in meteorological works.

The following few points of criticism are less concerned with the correctness of the book's statements than with the questions of what might have been included.

The description of the heat balance of the atmosphere seems to imply that the stratosphere loses heat to space through the so-called *W*-radiation (mostly wave-lengths greater than 14μ) without having it sufficiently replenished. The theory of Albrecht (briefly referred to on p. 105, but not accepted) concerning the breaking up of the *W*-radiation band into separate lines at low temperature and pressure is the only one to my knowledge that mitigates the difficulty, in that it makes the upper troposphere the place where there is a net loss of radiative heat and where a corresponding amount of heat can be received by advection and convection.

Brunt gives a very good and up-to-date description of synoptic meteorological problems. The map illustrations are well chosen, but they would have been still more convincing if they had been based on a denser network of land stations and as many ship observations as possible. The lack of detail in the maps is, however, partly overcome by the reproduction of autographic records from selected stations, which show good examples of the various kinds of frontal passages. (On p. 320, by mistake, autographic records from Valencia and Holyhead have been interchanged.)

Whereas the frontal description of the life-history of cyclones seems to have met with Brunt's approval, this is not the case with the attempt to formulate a mathematical theory of these phenomena. The reviewer agrees with Brunt in considering the waves of Helmholtz-Wegener (1921) and of V. Bjerknes (1921) as inadequate analogies to the nascent cyclones. Both of these are purely gravitational waves in horizontal surfaces of

discontinuity on a non-rotating earth. But it must be remembered that the contributions in question formed only the very first beginning of a general exploration of all possible small disturbances of an initial state of rest or of steady motion in the atmosphere. These disturbances have to begin with the character of stable or unstable waves. The stable ones remain small and unimportant, whereas the unstable ones grow larger and more intense. Unstable waves with wave-lengths as long as those observed in nascent cyclones were not found until the waves were transferred to a sloping surface of discontinuity on a rotating globe (Solberg, 1928–33). These waves, of a composite gravitational-inertial character, also show the following features: quasi-horizontal orbits of the air particles, periods longer than $12/\sin\varphi$ hours and uni-directional wave-propagation. Waves having all these properties seem to be justifiably analogous to the nascent polar front cyclones.

It is to be hoped that the wide field of atmospheric wave-motions, with its applications to tides, polar front and tropopause waves, wave-clouds and acoustics will be represented in a later edition of Brunt's book.

The reviewer's suggestions should of course not be taken as signs of severe criticism. After all, Prof. Brunt's book is in nearly all fields so masterly that it is bound to prove indispensable to all students of dynamical meteorology for many years to come. J. BJERKNES.

Kükenthal and Krumbach's Zoology

Handbuch der Zoologie:
eine Naturgeschichte der Stämme des Tierreiches. Gegründet von Prof. Dr. Willy Kükenthal. Herausgegeben von Dr. Thilo Krumbach. (Berlin und Leipzig: Walter de Gruyter und Co., 1932–35.)
(1) Bd. 2: Vermes Amera, Vermes Polymera, Echiurida, Sipunculida, Priapulida. Lief. 15. Pp. 113–240. 16 gold marks. Lief. 16. Pp. 193–320 + xiv. 18 gold marks. Lief. 17. Pp. 241–352. 14 gold marks. Lief. 18. Pp. 161–278 + xviii.
(2) Bd. 3, Hälfte 2: Chelicerata, Pantopoda, Onychophora, Vermes Oligomera. Lief. 4. Pp. 96. 12 gold marks. Lief. 5. Pp. 97–192. 12 gold marks. Lief. 6. Pp. 65–138 + 6. 10 gold marks. Lief. 7. Pp. 193–288. 12 gold marks. Lief. 8, Teil 1. Pp. 33–96. 8 gold marks.
(3) Bd. 4, Hälfte 2: Insecta 2. Lief. 1. Pp. 893–1036. 18 gold marks. Lief. 2. Pp. 1037–1132. 12 gold marks.
(4) Bd. 5, Hälfte 2: Tunicata. Lief. 1. Pp. 96. 12 gold marks. Lief. 2. Pp. 97–192. 12 gold marks. Lief. 3. Pp. 193–272. 10 gold marks. Lief 4. Pp. 273–400. 16 gold marks. Lief. 5. Pp. 401–544. 18 gold marks.
(5) Bd. 6, Hälfte 1: Acrania (Cephalochorda), Cyclostoma, Ichthya. Lief. 2. Pp. 113–208. 12 gold marks. Lief. 3. Pp. 209–336. 16 gold marks. Lief. 4. Pp. 337–448. 14 gold marks.
(6) Bd. 7: Sauropsida, Allgemeines; Reptilia; Aves. Hälfte 1, Lief. 2. Pp. 129–224. 12 gold marks.
(7) Bd. 7: Sauropsida, Allgemeines; Reptilia; Aves. Hälfte 2, Lief. 7. Pp. 657–768. 14 gold marks. Lief. 8. Pp. 769–899 + xi. 18 gold marks.

(1) THESE four parts complete the second volume of the "Handbuch der Zoologie". The fifteenth and seventeenth, about 230 pp., are devoted to an excellent account of the Hirudinea which is commendable for its attention not only to general structure and morphology, biology and development, but also to the neurones and other details of histology. About a third of the 300 illustrations are due to the senior author, Dr. J. A. Scriban. Appended is a list of rejected names of genera and species of leeches and the corresponding names now considered to be valid.

The sixteenth part contains the concluding portion of Prof. E. Bresslau's account of the Turbellaria. Regeneration and regulation, so much studied in the triclads, ecology and geographical distribution receive full consideration. A useful list is given of parasitic Turbellaria and their hosts. Prof. Bresslau and Dr. E. Reisinger have contributed a competent and well-illustrated account of the Temnocephalida.

In the eighteenth part is the excellent index to the entire volume.

This second volume, the publication of which has extended over nearly six years, is divided into two halves. The first half, which forms a volume of nearly 1,400 pages with a similar number of figures, contains the descriptions of the flatworms, Nemathelminthes, Rotifera, Gastrotricha and the Bryozoa Entoprocta. The second half is devoted to the Annelida and the Gephyrea and contains about 850 pages and 860 figures. The volume has been planned on a scale sufficient to enable the authors to deal with their respective subjects in a thoroughly adequate manner, and the result is a volume of great interest and usefulness.

(2) Of the five parts of the third volume noted above, one (the sixth) is devoted to the account of

the Onychophora (*Peripatus*) and the other four to some of the orders of Arachnida.

Dr. F. Zacher summarises present knowledge of the anatomy, geographical distribution and classification of the Onychophora and refers to some features of their biology, for example, their power of fasting and their mode of locomotion. Some reference to the histology of the alimentary canal might have been included. The paucity of our knowledge of the physiology of these animals emphasises the interest of the investigations now in progress.

The fourth, fifth and seventh parts contain accounts by Dr. A. Kästner of the Pedipalpi, Palpigradi, Ricinulei and Solifugæ (incomplete), and by Dr. Max Beier of the Pseudoscorpionidea. Both authors have given useful and adequate descriptions of the anatomy and biology of these orders and have contributed new illustrations.

Prof. Gerhardt contributes in the eighth part a useful account of the Xiphosura (*Limulus*) which, however, does not include notice of the interesting observations of Carlson and others on the physiology of the heart.

(3) Of these parts the first, by Dr. A. Handlirsch, is on the Hymenoptera and the second, by Prof. Meixner, on the Coleoptera (unfinished). The treatment of the morphology, natural history and classification of the Hymenoptera follows the usual lines. In the very brief section on physiology we do not find any information on the enzymes of the alimentary tract, on visual acuity and how bees recognise their own hive, or on the observations of von Frisch on colour vision, smell and taste in bees. Nor do we find any reference to the effects on external characters, sex and reproduction produced by the parasite *Stylops* in the Hymenoptera in which it is present, or to the occurrence of the Pupiparan *Braula* on bees.

(4) The first and second parts of the fifth volume (second half) contain a monograph of about 200 pages on the Appendiculariæ by Prof. Hans Lohmann, whose studies on these ascidians, extending over forty years and including the examination of collections from many expeditions, give him a special claim to write this account. He describes in detail the anatomy, development and biology of the members of this class and devotes a good deal of attention to the formation and structure of the 'house' of *Oikopleura*, to the ingoing and outgoing currents, and to the basket-work which forms the food-collecting mechanism. The geographical distribution and the classification (into twelve genera) are carefully considered, and in a useful diagram Prof. Lohmann represents eight stages in the probable evolution of the genera of the family Oikopleuridæ.

The third part begins with a brief general introduction to the natural history of the Thaliacea—*Pyrosoma*, *Doliolum* and *Salpa*—by Prof. G. Neumann, who has had long experience in the investigation of these floating ascidians. The emission of light by *Pyrosoma*, first seen by Péron in 1804, is discussed, and the recent work on the symbiotic bacteria in the mycetocytes in which the light is produced is carefully set forth. A detailed account of the Pyrosomida and the Cyclomyaria, in which the development and budding receive particular attention, is completed in the fourth part.

In the fifth part the last order of the Thaliacea (*Salpa* and its congeners) is well described by Prof. Ihle, who adds an appendix on the aberrant genus *Octacnemus* discovered by the *Challenger* Expedition and found only twice since then.

(5) Dr. V. Pietschmann provides, in these three parts, an account of the Cyclostomes which, however, will require at least one further part for its completion. Ninety pages, a disproportionate amount of space, are devoted to the account of the structure of the brain and spinal cord, including studies of the neurones from the work of Retzius and other neurohistologists. The numerous illustrations are well chosen and excellently reproduced.

(6) Dr. Otto von Wettstein completes his description of the anatomy of *Sphenodon*, the nervous system, sense organs, alimentary respiratory, vascular, excretory and reproductive systems being successively considered. The development is briefly sketched, the fossil relatives of *Sphenodon* are discussed, and what is known of the biology of the animal is adequately summarised.

(7) In these two parts, Prof. E. Stresemann's important volume on the birds is completed. In the first fifty pages are discussed the many aspects of migration, and examples of various kinds of migration are described. Among the examples of long flights in migration he states that it appears almost impossible that a snipe, *Capella hardwickii*, should fly without resting, twice in the year, from its breeding place in north Japan to its winter quarters in eastern Australia and Tasmania, where it lives from September until January. The distance between its two homes is 5,000 km. and the bird has never been found in any intermediate station. The work done on a shorter migration by a moderate-sized plover, *Charadrius dominicus fulvus*, flying from the Aleutian Islands to its winter quarters in the Hawaiian Islands, the shortest passage between which is 3,300 km., is represented by about a quarter of a million strokes up and down of the wings. The bird is estimated to travel 26 metres a second and to make two strokes of the wings a second over the flying period of

35 hours. Estimates for other birds give periods of pauseless flights of 40–48 hours. The reserves available in the body to meet this great demand for energy are fat, glycogen and protein, of which fat is by far the most important. Writing of the heights attained by birds, the author records that two British aviators saw two large birds, probably cranes, at a height of 15,000 ft., that a flock of rooks was once observed at 11,000 ft. and that plovers were seen at more than 5,000 ft. But, according to aviators, birds fly as a rule at a height of less than 1,000 metres and the smaller ones below 300 metres. This part of the work is of great general interest.

A list is given of the helminthes and arthropods parasitic in or upon birds and, in connexion with the Mallophaga, a brief consideration of these insects as possible indicators of the affinities of their hosts, leads to the conclusion that such a method must be applied with the greatest care and that at least one of the cases cited cannot be supported.

The classification which follows contains also notes on structure and biology, and is illustrated by drawings of skeletal and other anatomical features and by photographs of birds in Nature.

Prof. Stresemann's volume of 900 pages is a well-balanced and exceedingly interesting account of the structure and life of birds.

When the first part of this "Handbuch" was published nearly ten years ago, the work was advertised to be completed in five volumes. It has expanded to seven volumes, each of which except the first is divided into two halves. It would be of advantage to many subscribers if the editors and publishers, who are probably now within sight of the end of their labours, could give some idea when the remaining parts of the work are likely to be completed. Meantime we offer them, and the contributors of the parts above noted, cordial congratulations on the high quality of their work and on the extent of the output during the last three years.

Stainless and Chromium Steels

(1) The Book of Stainless Steels:
Corrosion resisting and Heat resisting Chromium Alloys. Edited by Ernest E. Thum. Second edition. Pp. xii+787. (Cleveland: The American Society for Steel Treating, 1935.) 5 dollars.

(2) Chromium Steels
By Dr. Richard Henry Greaves. (Department of Scientific and Industrial Research.) Pp. vi+321+4 plates. (London: H.M. Stationery Office, 1935.) 7*s*. 6*d*. net.

(1) THE introduction of steels having a high resistance to corrosion is probably the most important advance made in the metallurgy of steel in the last twenty-five years. Beginning with the invention of 'stainless' cutlery steel by Brearley, the range of composition of corrosion-resisting steels has been widened, until now products having the most diverse mechanical properties have been obtained. By using nickel and chromium together and keeping the percentage of carbon low, alloys are made which can be pressed, drawn, or otherwise worked without injury to their chemical properties. It was found, however, that exposure to high temperatures, either over long periods as in superheater tubes, or intensely for a short time as in the making of welded joints, may cause a peculiar kind of brittleness, and much research was necessary to find means of overcoming this difficulty, mainly by the addition of small quantities of other elements.

In the present work, which has soon reached a second edition, steels of this class are discussed from every point of view by a large team of authors. The manufacture, constitution, properties and uses in the engineering and chemical industries are fully discussed, and the precautions to be taken in welding and in the construction of plant are explained with great thoroughness. As is natural in such a composite work, there is some overlapping, and the contributors do not always agree on matters of detail; but in general the information proves on testing to be full and accurate. It may be mentioned that eleven pages are occupied by a list, classified according to composition, of the trade names of the 'stainless' steels, although only American brands are included.

(2) Chromium is an essential component of steels of the stainless class, but it also enters into the composition of many other steels of technical value, among them the nickel-chrome steels so widely used in engineering. The simple chromium steels, except perhaps those used for ball-bearings, are less frequently discussed, and Dr. Greaves has rendered a valuable service in presenting so detailed an account of their properties. Many of the experimental data are derived from work at the Research Department, Woolwich. The information is clearly given, and illustrated by excellent photomicrographs. Full references at the end of each section make it easy to consult the original publications.

The Fundamentals of Chemical Thermodynamics

By Dr. J. A. V. Butler. Part 1: Elementary Theory and Electrochemistry. Second edition. Pp. xv+253. (London: Macmillan and Co., Ltd., 1935.) 7*s*. 6*d*.

In the second edition, the general plan of this book has been retained, but several chapters have been rearranged and partly rewritten. This revision has improved the utility of the book. About fifty pages of new material have also been added. These include a discussion of heterogeneous solid–gas equilibria, dealing with the carbon–oxygen reaction and its participation in the blast furnace; the methods of electrometric hydrogen ion determination and potentiometric titrations, which are very briefly dealt with; oxidation-reduction indicators, which are briefly but clearly explained; and a section on electrolysis which includes a discussion of over-voltage from the modern point of view.

It is doubtful whether the treatment of freezing point depression on p. 76 has any advantage over the usual one, in which the thermal properties of the solution are eliminated, since no proof of the validity of the second equation is given. The name 'isochore' applied to an equation for constant pressure (p. 98) seems misplaced. The author adopts the American definition of free energy and introduces the term 'net work' for its diminution, that is, the actual work minus the work done against external pressure, which seems a useful procedure. The book is clearly and accurately written, and the new edition is likely to increase its popularity and usefulness.

The Discovery of Specific and Latent Heats

By Dr. Douglas McKie and Niels H. de V. Heathcote. Pp. 155+6 plates. (London: Edward Arnold and Co., 1935.) 6*s*. net.

This scholarly treatise emanates from the School of History, Methods and Principles of Science at University College, London, and its authors must surely have devoted many hours of patient study and research among the original eighteenth century works in order to obtain the material for their book. As Prof. E. N. da C. Andrade, in his eulogistic preface points out, the subject of the book is no less than the very foundation of the modern science of heat. Most of the writings to which reference has been made have been consulted in the original languages, including the Swedish of Wilcke. The authors have established by these studies that his work, while independent of Black's, was "both later and less satisfactory". The credit for the discovery of specific and latent heat may therefore be fully attributed to Black.

Portraits of the leading figures are reproduced; some of the lesser-known ones have only been secured after much trouble. A valuable feature of the book is the inclusion of extracts from the originals, showing the care and trouble with which these early experiments were carried out. It has often been urged that present-day students should study the early masters, and this book provides a convenient means so far as the subject of heat is concerned. H. R. L.

Research: the Pathfinder of Science and Industry

By T. A. Boyd. Pp. xvi+319. (New York and London: D. Appleton-Century Co., Inc., 1935.) 10*s*. 6*d*. net.

In this volume the author tells in a pleasing way just what research is, and what the ordinary research worker does. The book is divided into five parts. In the first, the distinction between pure and applied research is explained; in the second the organisation of modern research and the general lines followed are discussed, including useful sections on the financing of the projects and the selling of the results. The third and fourth sections, "Men" and "Qualifications", contain information which must prove of value not only to those responsible for appointing the staffs of laboratories but also to those anticipating scientific research as a career. Part V, "Achievement", should prove a fruitful source of replies to those who doubt the wisdom of spending time and money on research. Part VI consists of miscellaneous essays.

The reading is apt to be a little discontinuous owing to the continual introduction of anecdotes and quotations, some of which are repeated more than once. *Bons mots* uttered by certain leading American directors of research laboratories are also liberally sprinkled throughout the book. The value of these excellent essays might have been enhanced had the author included information and facts concerning present-day research in countries other than America; it would have been of value to read in such a book some of the important pronouncements of a few of the leading European directors of research, alongside those of their American contemporaries. H. R. L.

Principles of Mechanism

By Prof. C. E. Pearce. Pp. ix+283. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1934.) 21*s*. 6*d*. net.

Intended to be used as a textbook in classes entering upon the study of mechanisms and having little familiarity with the details or operation of machinery in general, Prof. Pearce's "Principles of Mechanism" provides a useful elementary survey of the subject. The matter is much more on the practical side than the title suggests, and the arrangement is designed to lead up to the general principles through a detailed discussion of a number of the more important and representative applications such as: friction, toothed and screw gearing; belt, rope and chain drives; intermittent motions; ordinary and epicyclic wheel trains. Then, after explaining in detail and by numerous examples the method of analysis by centro or virtual centre, the author concludes with linkages, cams, and the geometrical problems involved in straight line motions, motor-car steering gears, etc.

While the book as a whole deals with matter which is not new, the author has succeeded, by his arrangement of the subject, the explanatory text and the examples chosen, in putting it before his readers attractively and convincingly. A valuable feature for the student is the comprehensive range of problems presented for solution. J. A. C.

The Rev. John Kerr, F.R.S., Inventor of the Kerr Cell

By Dr. Robert C. Gray

ONE of the many problems in television reception is that of modulating the brightness of the spot of light that, travelling very rapidly over the screen, gives the sensation of a completely moving picture. In one system a neon lamp is used, and the brightness of the lamp is varied by the incoming signals being allowed, after suitable amplification, to alter the voltage across the lamp. A neon lamp is not very bright, compared with a filament or arc lamp; and the next development was the use of a bright lamp, the brightness of the beam of light being altered after the light had left the lamp.

The first experimenters who tried this latter method found that the necessary apparatus was already available in the Kerr cell; it had been invented in 1875 by a Glasgow man, and had been lying for more than fifty years awaiting a practical application.

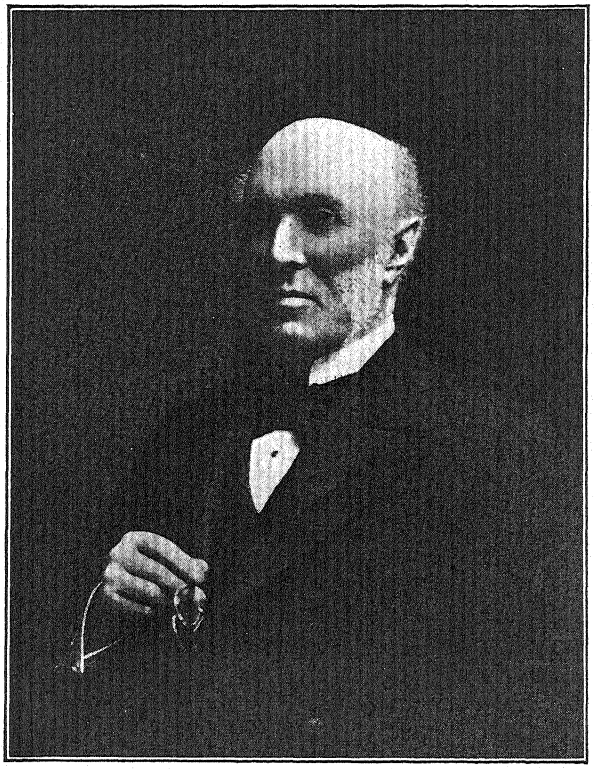

FIG. 1. The Rev. John Kerr, M.A., LL.D., F.R.S. (1824–1907).

John Kerr was born at Ardrossan, Ayrshire, on December 17, 1824. He was the second son of Thomas Kerr, who owned a fleet of fishing vessels, and he received part of his education in a village school in Skye. He entered the University of Glasgow in 1841 as a divinity student, and took the usual classes for the degree of master of arts. During the session 1845–46, he took the class of natural philosophy, when it was taught during the illness of Prof. Meikleham by David Thomson, afterwards professor of natural philosophy at Aberdeen. In 1846 William Thomson, who later became Lord Kelvin, was appointed to the chair of natural philosophy. William Thomson was only six months older than Kerr, and there sprang up a close friendship between these two young men, professor and student, each twenty-two years old, a friendship that was to last for more than sixty years until their deaths, within four months of one another, in 1907. Kerr continued his studies in physics under Thomson for three more years, gaining special prizes, in successive years, on the subjects of "The Mathematical Theory of Magnetism", "The Mathematical Theory of Electricity", and "The Distribution of Electricity on Spherical Conductors". He graduated master of arts in 1849, eight years after his first matriculation, "with Highest Distinction in Mathematics and Natural Philosophy", and was awarded the Earl of Eglinton's Prize of twenty sovereigns as the most distinguished student in mathematics and natural philosophy. He engaged in teaching for some time, and was ordained to the ministry of the Free Church of Scotland, but did not preach very often.

In 1857 Kerr was appointed lecturer in mathematics and physical science in the Free Church Training College for Teachers, Glasgow. In 1863 he published a pamphlet entitled "The Metric System: its Prospects in this Country", and in 1867 a book on what he called "Rational Mechanics". In the following year the senate of the University of Glasgow, on the recommendation of Profs. Thomson and Blackburn, conferred on Kerr the honorary degree of doctor of laws.

From 1848, Prof. Thomson was gradually converting what had been the old professorial wine-cellar into a physical laboratory for students, the first in the world. Thomson invited his students to help him in his measurements, and Kerr was one of the earliest members of the pioneer team, composed, strangely enough, mostly of divinity students. This experimental training under an

enthusiastic leader had a great influence—as such training generally has—on Kerr's after-life, and when he joined the teaching staff of the training college, he utilised a cellar there for experimental work. Afterwards he worked in the basement of his house. He was fifty-one years of age when in 1875 he made his first and most important contribution to science, by a publication, in the

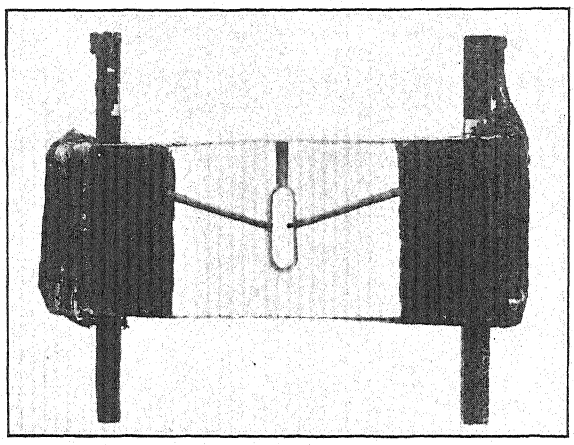

FIG. 2. The first Kerr cell, used by Dr. John Kerr in his discovery of the Kerr electro-optic effect.

Philosophical Magazine, of the discovery of what came to be known as the Kerr electro-optic effect. It is this effect that is utilised in the Kerr cell used in television reception. Faraday in 1834 thought that this effect might exist; he tried to detect it, but failed. William Thomson in 1845 suggested that it might be worth while to search for the effect; his attention was directed to Faraday's negative result, and he abandoned the idea. Thirty years later, Kerr looked for the effect, and found it, first in glass, later in certain liquids.

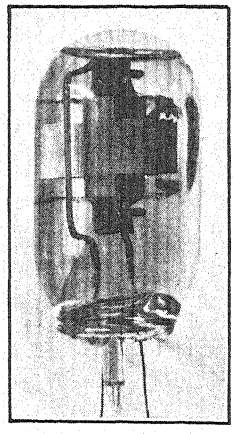

FIG. 3. Kerr cell (1935) as used by Baird Television, Ltd., in television reception.

The original piece of apparatus with which Kerr detected the effect in glass was a simple slab of glass, measuring six inches by three inches, and three quarters of an inch thick; two collinear holes, each an eighth of an inch in diameter, were drilled from the two ends, parallel to the long edges, the ends of the holes being about half an inch apart. Down each of these holes was passed a wire from one pole of an induction coil, and polarised light was passed from one face of the slab to the opposite face. When the induction coil was operated, Kerr found, as he expected, that the glass had become doubly refracting. He followed up this discovery by searching for, and finding, the same result in liquids. The original cells that he used are in the care of the University of Glasgow, and a photograph of the first cell used for liquids is reproduced as Fig. 2. For comparison, a photograph of a modern Kerr cell is also reproduced (Fig. 3). In the original Kerr cell, the cavity in the centre was closed at the sides by plates of glass, and was filled with liquid through the channel drilled from the top; wires that carried the varying electric potential will be seen passing down the sloping holes; polarised light was passed through the liquid from one side of the slab to the other. In the modern Kerr cell, the voltage is applied between two sets of alternate plates; the liquid used is nitrobenzene, and the light is passed through the liquid in a direction parallel to the planes of the plates. When in 1898 Lord Lister, president of the Royal Society, was presenting a Royal Medal to Dr. Kerr, Lord Lister said: "It has been a matter of admiration and wonder to subsequent investigators that Dr. Kerr should have been able to learn so much with the comparatively simple and ineffective apparatus at his disposal". It is related that Dr. Kerr, then seventy-four years old, was much peeved at Lister's remarks: "Simple it may be," he protested, "but not ineffective; rude, but not crude".

In 1876 the British Association met in Glasgow, and Kerr read a paper on his second discovery, the Kerr magneto-optic effect, which has been of much importance in the theory of magnetism. Altogether Kerr published, between 1875 and 1901, only ten papers, but each is of permanent value. In 1890 he was elected a fellow of the Royal Society, and in the following year Sir Arthur Rücker, speaking at the British Association, referred to Kerr's outstanding discoveries and said: "The generations which reap the harvest which earlier students of the science of electricity have sown will not forget the name of Dr. Kerr as that of a physicist who completed in the laboratory of a training college a chain of evidence of which Faraday and Maxwell had forged the first links". In 1898 the Royal Society awarded him the Royal Medal, now in the Hunterian Museum of the University of Glasgow. At the dinner that followed the presentation of medals, Sir Oliver Lodge, who had been awarded the Rumford Medal at the same time for his researches in radiation, replied for the medallists; speaking of Dr. Kerr, he said that Dr. Kerr had made two first-class discoveries in science, and his name would go down to posterity linked with these discoveries for all time; ten centuries later the Anglo-American race would know and remember the name of their medallist, John Kerr. Kerr retired from his lectureship at

the Training College in 1901 after forty-four years' service. His country recognised his work by giving him, in 1902, a Civil List pension of £100 a year. He died on August 18, 1907, three months before Lord Kelvin, in his eighty-third year.

Dr. Kerr was a well-built man, over six feet in height, of attractive and lovable personality. The late Prof. Andrew Gray wrote of him: "The name of this quiet and unostentatious teacher and experimentalist will be linked for all time with that of Faraday. He would not himself have desired any better immortality"; and Prof. Magnus Maclean, who had been a student under Kerr and is still with us, said at Kerr's retirement: "No one could have passed through Dr. Kerr's class without observing and being influenced by the singular simplicity, the sincerity and the lovableness of his character".

The Draft Poisons List and Poison Rules

The Chemical Manufacturer and the Chemist

Interpretation of the Rules

THE report of the Poisons Board together with the draft Poisons List and Poison Rules, which was discussed in NATURE of June 22, p. 1013, raises a number of questions of detail of interest to many besides the pharmacist. The more important of these questions are those which affect the chemical manufacturer particularly, and those which concern the profession of chemistry as a whole.

The first set of questions was considered at a meeting convened by the Association of British Chemical Manufacturers on July 4, which was attended by Mr. M. D. Perrins, secretary of the Poisons Board, to discuss the interpretation of the draft Poisons List and Rules. At the outset, Mr. Perrins pointed out that the only real distinction between Part I and Part II of the Poisons List, that between poisons which can be sold by retail to the general public by authorised sellers of poisons, that is, by registered pharmacists, and those which can be so sold only by listed sellers and authorised sellers of poisons, does not affect the sales with which the chemical manufacturer is concerned. The distinction between substances in the First Schedule and those which are not is, generally speaking, that those in the First Schedule have various restrictions applied to them, such as that the purchaser must be known to the seller and a record must be kept. On the other hand, for practical purposes, the only restriction on substances not in the First Schedule is that they must be labelled in accordance with the Act and Rules and they must be in the type of container required by the Rules.

Mr. Perrins also pointed out that preparations sold by manufacturers to doctors or veterinary surgeons more or less in bulk do not come under the heading of medicines 'made up ready', and emphasised that the Rules are to be administered by those who could be trusted to act with commonsense. The view taken in the report of the Departmental Committee is that the control of poisons is such an intricate and complicated matter, so liable to change, that it is impossible to deal with it by restrictions set out in an Act of Parliament. Much elasticity is necessary and questions of control must be dealt with by regulations which can be altered from time to time. Should it be found, for example, that these Rules work harshly on the trade in a particular raw material which does not in practice afford any danger to anyone, a fact which may have been overlooked, then that can be dealt with by a Rule adding it to the general exemptions or special exemptions as may be required.

In the discussion which followed, a number of points were raised in regard to the detailed interpretation of the Rules. It was emphasised that there are no responsibilities placed on the manufacturer as to whom he sells poisons, provided he does not sell them by retail to members of the public.

The question of abbreviated names was raised, the abbreviations used in the British Pharmacopœia being regarded as official, and it was suggested that the Association should recommend that the ordinary abbreviated names used in the trade should be considered to be accepted scientific names, a proposal which will not commend itself to the profession of chemistry generally. Various questions relating to transport and labelling were raised, but as the Report itself emphasises, the Board does not propose to include any industrial poisons in the List solely on the ground of the possibility of danger arising during transit, in view of the rules to be issued under the Petroleum

(Consolidation) Act, 1925, for the control of the transport by road of dangerous liquids and liquefiable gases.

It was pointed out that as Rule 20(*a*) stands, analytical laboratories which cannot claim to be engaged in education or research must have their bottles fluted, and it was suggested that samples used in examinations do not constitute supply and accordingly need not be specially labelled.

The second set of questions has been raised in a letter in *The Times* of July 6 by Prof. E. C. C. Baly and relates to the qualifications to be possessed by those authorised to supervise or control the manufacture of poisons and particularly to the nature of the prescribed qualification in chemistry. Prof. Baly points out that in Paragraph 65 of its Report, the Board, after recommending that the control of the manufacture of pharmaceutical preparations for the internal treatment of human ailments should be restricted to registered pharmacists, medical practitioners, fellows and associates of the Institute of Chemistry, and persons who have been continuously engaged in the control of the manufacture of pharmaceutical preparations for a period of three years, makes the erroneous statement that there is in Great Britain no recognised body other than the Institute of Chemistry that issues certificates or other documentary evidence of competency in chemistry as such. Not only does the British Association of Chemists issue such documentary evidence but also the universities, and the Report refers to university degrees and diplomas in such a way as to suggest that a university degree does not confer competency in chemistry as such.

Prof. Baly also directs attention to the suggestion in the Report that the societies named are included because they can exercise disciplinary action by removing a name of a member guilty of unprofessional conduct. Exactly the same action can be exercised by the British Association of Chemists, and Prof. Baly emphasises that the statements in the Report are the more unacceptable to a large body of chemical opinion because the Institute of Chemistry does not represent more than 40 per cent of the chemists in Great Britain.

In a reply in *The Times* of July 11, Sir Gerald Bellhouse points out that the proposed rule only applies to the manufacture of pharmaceutical preparations for the purposes of the internal treatment of human ailments, and not to the manufacture of the ingredients of the composition. The statement regarding the Institute of Chemistry, challenged by Prof. Baly, was primarily a reference to the fact that the Institute of Chemistry is the only institution connected with the profession of chemistry which has acquired the right, granted by Royal Charter, to confer definite qualifications in chemistry. The Board's recommendations in regard to the supervision of manufacture should be considered in regard to all the various legal and administrative questions set out in Paragraph 65 of its Report.

Norwich Meeting of the British Association

Final Programme

THE full programme of the Norwich meeting of the British Association should be in the hands of members next week, if they have intimated intention to be present. The programme has taken shape no less effectively than usual out of the general plans which were prepared at the meetings of organising sectional committees in January last. There is no doubt that the now regular practice of calling all these committees to meet early in the year on one day and in one place (recently, Birkbeck College, London) is the most successful administrative reform introduced into the working of the Association in recent years. It has had a notable effect upon the co-ordination of the final programme, which was urged as desirable in the columns of NATURE shortly after the Association had resumed its post-War activities. It is due to the memory of the late general treasurer, Dr. E. H. Griffiths, to associate his name with this exceedingly valuable measure : he introduced it.

The subjects of the presidential addresses have been indicated in an earlier notice (NATURE, May 11, p. 778). They range as usual from strictly technical essays in the pure sciences to those to which the layman will listen with ease, such as that of Dr. Pickard-Cambridge under the provocative title of "Education and Freedom". Some of the addresses will introduce discussions in their Sections : examples are that of Prof. W. N. Haworth on the molecular structure of carbohydrates, Prof. F. Balfour-Browne's on the

species problem, and Dr. J. A. Venn's on the financial and economic results of State control in agriculture.

Most of the sections have developed the practice of ranging many, if not all, of the communications they are to receive under specific headings of discussions or symposia: it is probable that sufficient opportunity is still left for independent speakers on their own individual subjects; and the provision of major topics adds weight, and, from the public point of view, interest to the programme. One can even conceive of lay members finding their way to Section C (Geology) for the sole purpose of discovering what is meant by rank in coal. Nor should even these members, the cultivation of whose interests is a first charge upon the Association, be neglectful of the opportunities offered by such discussions as those in Section A on nuclear physics (to be opened by Lord Rutherford) and on new stars; the geological relations of early man in East Anglia, or, again, denudation chronology (Section C); and the herring problem (Section D).

Our previous article has referred to other discussions which need not be recapitulated; but the bald titles set out in the preliminary programme issued last May are now found to have concealed unexpected interests. For example, the subject of noise then entered under Section A is seen to indicate a demonstration lecture by Dr. G. W. C. Kaye involving elaborate and generous preparation. Films now find their regular place in Association programmes, thanks to the help of those who are willing to lend and demonstrate them, though it is to be feared that arrangements for showing them must have added to the task of the local executive. The Department of Industrial Co-operation has in its programme films illustrating industrial-educational and industrial management features. Dr. Sydney Long will show to the Conference of Delegates of Corresponding Societies a film illustrating the Norfolk bird sanctuaries. Section D (Zoology) has an afternoon and evening devoted to film work, including Col. Seymour Sewell's lecture on the John Murray Expedition to the Arabian Sea, Prof. Julian S. Huxley's "Private Life of the Gannets", and an exhibit by British Gaumont Instructional Films. The Gaumont-British Corporation, Ltd. will show to Section L (Educational Science) films illustrating physical education.

Both Norwich and the neighbourhood have taken advantage of the readiness of the Association to provide public lectures if desired. Sir Arnold Wilson will speak at Norwich on "Science and Population Problems", and Prof. W. Garstang will speak to young people on the songs of birds. There will be external lectures at Cromer, Fakenham, Yarmouth, King's Lynn, Lowestoft and Thetford, and the speakers will be Mr. A. Corless, Dr. B. A. Keen, Mr. M. Graham, Prof. A. Ferguson and Prof. W. T. Gordon.

The "Scientific Survey" which now, on a systematic plan, is published annually in lieu of the old local handbooks (which, however excellent in themselves, followed no model) will cover briefly every scientific aspect of Norwich and its neighbourhood. Of the unusually extensive interests of the district, the ample and wide-ranging series of sectional excursions affords evidence. In addition to the usual publications connected with the meeting, it should be observed that through the generosity of Sir Sidney Harmer copies of the paper and the fine map dealing with the distribution of erratics and drift, by his father, the late F. W. Harmer, will be available for distribution in the geological and geographical sections (C and E); furthermore, the local committee will provide for distribution in Sections E (Geography) and M (Agriculture) copies of the appropriate maps prepared by the Land Utilisation Survey.

In addition to the customary civic reception by the Lord Mayor and Lady Mayoress, which will be given in the quite unusually fine setting of the Castle Museum, there will be a garden party given by H.M. Lieutenant for Norfolk, Mr. Russell Colman, and Mrs. Colman, in the beautiful grounds of Crown Point. It is satisfactory to notice that an attempt is made to keep the time of this engagement, which falls on the Tuesday afternoon, clear of the encumbrance of official engagements. The usual hour of the Committee of Recommendations has been advanced, and the final meeting of the General Committee will be held on the last Wednesday at noon, instead of the Tuesday afternoon. There will also be a garden party at Norwich Aerodrome, when special displays will be given by the Royal Air Force in conjunction with the Norfolk and Norwich Aero Club.

Among other amenities connected with the meeting, the programme indicates the floodlighting of the Guildhall, the Castle Museum and some of the buildings adjacent to the Cathedral.

As not uncommonly happens, there is an unnecessary impression abroad that lodging accommodation will be difficult to obtain in Norwich. It is true that the hotels are full, and so will be the Training College hostel, but other accommodation can still be obtained, and is not likely to fall short, while for those whose freedom of action permits of their spending their nights in one of the coast resorts, special railway facilities are promised.

Obituary

Mr. G. E. Collins

THE melancholy accident on July 30 that deprived England of a soaring pilot of international reputation has also caused a serious loss to meteorology. Mr. G. E. Collins only began gliding in 1932, and with extreme rapidity acquired very great technical skill. But above all he had insight and imagination: he was always trying to increase, and to apply, our knowledge of air-currents. He was in close touch with some of the finest German pilots, and like them made use of cumulus clouds and 'fronts' to gain height that could be converted into horizontal travel. He learned from Wolf Hirth the method of soaring in a spiral in a 'thermal' (an up-current without a cloud to mark it) by the use of a variometer, steering in the direction in which the uplift was greatest; but he soon discovered a method of soaring in thermals without a variometer, using his body sensations and steering towards the wing which was the more strongly lifted. To-day probably a dozen British pilots can climb in thermals, but they owe much to Collins's peculiar gifts.

Collins was among the foremost to make use of the up-currents suggested by theory under the long lines of cloud that form parallel to the wind direction, realising their value for flights down-wind. Accordingly, in August 1934 he employed these 'cloud-streets' in a flight of 98 miles from Dunstable to Holkham Bay, still the British record: he reached the Norfolk coast at a height of 3,000 ft., and showed that it is only the dimensions of our island that impose the limit on cross-country flights.

In July last year, Collins extended ideas by providing a reply to the criticism that gliders can only sail down-wind. In a flight in a west-south-west wind, he passed over Watford and alighted at Hanworth, due south of it; his speed relative to the air was not only much faster than the wind, but its direction must have been within 45° of straight into it. Now that tacking is possible, much can be done.

It had been hoped that Collins's skill might have been employed in carrying self-recording instruments round and through clouds in order to get much needed data procurable in no other way; may his fine example inspire others to take up this work.

G. T. W.

Dr. Helen Chambers

BY the death of Dr. Helen Chambers on July 21, Great Britain has lost one of its most devoted workers in the cause and treatment of cancer. She received her medical education at the London School of Medicine for Women, took her M.B. with first-class honours in 1903, and was a gold medallist. At twenty-four years of age, she was appointed pathologist to the Royal Free Hospital, a post she held until 1915, when she resigned to take up a similar position at the Endell Street Military Hospital. Before the War she had been doing part-time research work in the Cancer Research Laboratories of the Middlesex Hospital, and when the military hospital closed she accepted full-time work there under the Medical Research Council.

Only the comparatively few people who came into intimate touch with Dr. Chambers realised her full value. Her wide experience of general pathology and extraordinary ability to concentrate entirely on the matter in hand made her invaluable for research work. It was mainly due to her foresight and inspiration that the Marie Curie Hospital at Hampstead came into being. She realised that for satisfactory radium treatment it was essential to have the close co-operation of surgeon, physicist and pathologist, and the excellent results of treatment of uterine cancer at that hospital show to what an extent she succeeded in securing this collaboration.

Dr. Chambers contributed many papers to the scientific press on the effects of radiation on malignant and normal cells. The fact that animals, after the absorption of malignant tumours which had been very accurately irradiated, were often immune to tumour growth was always at the back of her mind for its possible clinical application. So recently as last winter she spent several months in Paris, where she carefully studied the X-ray treatment of cancer of the breast by Prof. Coutard, whose methods she felt gave more hope of attaining this desired effect than any other treatment of the disease in use at the present time.

Mr. J. H. Ronaldson

JAMES HENRY RONALDSON, who died on August 5, was a very well-known and much respected consulting mining engineer and geologist. He was born in the county of East Lothian and received his scientific and technical education at the Universities of Edinburgh and Liège. He travelled widely, but was probably best known in Australia and South Africa, where he had resided for comparatively long periods. He made London his headquarters as from 1910, and his business, until the outbreak of the Great War, took him to all sorts of countries. Shortly after the outbreak of the War, he found himself in the Ministry of Munitions, but after a short period of service there, Messrs. Brotherton and Co., Leeds, who had gone in for the manufacture of munitions, applied for his services, and he supervised their manufacture of explosives until 1918. After that he continued his practise, and for a few years was associated with Dr. William Cullen in consulting business.

Ronaldson was not only an excellent mining engineer but also a very good geologist, and it was this happy combination which made his reports so valuable to those who employed him. Moreover, he was the soul of integrity, and he never allowed

himself to be carried away by the influence of others who may have examined the same property. His clients, therefore, knew that when he prepared a report it was an honest one, and uninfluenced by expectations on one side, or performances on the other. Although he was connected with many scientific and technical institutions, he was never addicted to the writing of papers. Indeed the only one on record is a joint one by Dr. Cullen and himself, which deals with a purely technical aspect of mining, but which is still of reference value.

He did not take an active part in discussions on technical subjects, but whenever he did intervene he was always listened to with great respect, because his audience recognised that his experience covered a very wide field.

News and Views

Dr. Griffith Evans's Centenary

DR. GRIFFITH EVANS celebrated his hundredth birthday by an at home at Bangor on Wednesday, August 7 (see NATURE of August 3, p. 173). He had on the previous evening been visited by two veterinary colleagues, Capt. W. H. Savage and Sir Frederick Hobday. Although, through the bad luck of two very severe accidents involving fracture of each thigh, Dr. Evans is bedridden, his mental faculties are wonderfully alert. In accordance with his own request the presentation from his Alma Mater, the Royal Veterinary College, was the first of the series of the ceremonies which had been arranged to do him honour. Sir Frederick Hobday, in presenting the congratulatory scroll, said: "As a great pioneer we are proud of what you have done for veterinary science and we wish you continued good health to see still further, for many years to come, the progress in comparative medicine—which was initiated by the discovery you made of the parasites in the blood—when investigating (whilst a veterinary officer in the British Army) the disease known as 'surra' in horses and camels". The presentation scroll is framed in a piece of the wood of the old College. In acknowledging the presentation, Dr. Evans referred to his early years at the Royal Veterinary College and recalled characteristics of his teachers, Profs. Spooner, Simmons and Morton. After this address, a telegram sent on behalf of Their Majesties the King and Queen was handed to Dr. Evans; it read as follows:—"The King and Queen are much interested to hear to-day you are celebrating your hundredth birthday, and desire me to convey to you their hearty congratulations. Their Majesties are aware of your distinguished services to veterinary science and send you their best wishes on this great anniversary." Telegrams of congratulation were also received by Dr. Evans from H.R.H The Prince of Wales, Mr. Lloyd George, the Council of the Royal College of Veterinary Surgeons, and the citizens of Bangor, among others.

Unknown Papua

A SURVEY expedition to northern Papua under Mr. J. G. Hides, assistant resident magistrate, and Mr. James O'Malley, patrol officer, returned to Port Moresby on July 20 after an absence of eight months, in which at the cost of great hardship much previously unexplored country was crossed, and unknown groups of natives encountered. The area explored lies between the sixth and seventh parallels of south latitude and the 142 and 114 meridians of east longitude. The party started in December last, travelling up the Fly and Strickland Rivers and then along the Carrington River, an unexplored tributary of the Strickland, until navigation became impossible. Boats were then abandoned, and the expedition struck across country overland for the Purari River, which was reached after an arduous four months in which the party was reduced to the verge of starvation, owing in part to the attitude of the natives who, though at times graciously friendly, at other times refused them food and generally displayed an attitude of contemptuous and thinly veiled hostility.

ACCORDING to an account of the expedition which appeared in the Melbourne *Argus* of July 23, after leaving the Carrington, the party in twenty days passed through a desolate limestone barrier and penetrated a vast fertile valley, 20–30 miles broad, under cultivation by a large population of short, brown-skinned, mop-haired people of an "Asiatic type", calling themselves Tari Furora. Both men and women till the ground, using wooden spades. They refused gifts of steel. No communal villages were observed, and the people seem to live in individual families. The same people were found on a high grass tableland traversed in April and May, where an estimate of their numbers is given as 100,000. As the party travelled east and south-east the type gradually changed and men were observed wearing bear's tusks as nose ornaments. A preliminary report on the expedition's work has been presented to the Lieutenant Governor, Sir Hubert Murray. An official account was published in Australia on August 13, and an account appears in *The Times* of August 14.

Further Discoveries at Colchester

EXCAVATION, resumed on the Romano-British site at Colchester early in July, continued to produce evidence, mainly in the form of pottery, of the importance of the pre-Roman city as a centre of foreign trade and native British industry. Early in

August, however, investigation was given a fresh impetus by the discovery of vestiges of a remarkable character of what at first sight was thought to be a building of considerable size, assigned tentatively to the last decade of the first century A.D., on the evidence of a coin found on the floor of what appeared to be a kitchen. Further excavation showed that this identification of the character of the structure was premature. The new discovery can now be seen to be of far greater importance, and indeed, in certain respects it seems unique. The wall, so far as at present uncovered, a distance of some 230 ft., according to a report in *The Times* of August 10, runs east and west almost in a straight line. The foundations, which remain *in situ* to a height of several inches, vary in breadth from 2 ft. 6 in. to 3 ft. At regular intervals of 17 ft. on both faces of the wall are small buttresses, 2 ft. square in plan. The method of construction is interesting. It points to a severe economy on the part of the builders, no doubt owing to the scarcity of suitable stone in East Anglia. The core of the wall is composed of a coarse gravelly rubble with a frequent mixture of broken amphoræ, mortaria and roof-tiles. Only a few fragments of the stone coping remain. The excavators hesitate to offer any conjecture as to the purpose of the wall; but they are of the opinion that it is probably unique in the British Isles.

Civilian Respirators

UNDER the title "Civilian Respirators" an article in the August issue of the *Industrial Chemist* discusses the general requirements of apparatus for the protection of the civilian population in the event of hypothetical hostilities involving the use of lethal gases. It is well known that public opinion is divided on the question whether it is desirable to discuss these matters in the present temper of Europe. Some hold that peace is endangered by even humanitarian preparations in case of war; others consider that it would be folly to ignore the possibilities of a new form of warfare, and that common prudence dictates the examination of all measures necessary to combat it. In any event, if measures are to be taken, it is at least common sense to take the best available; and in this matter of the design of respirators suitable for civilian use, the article to which we refer suggests to potential inventors the following general requirements: (1) A canister should be attached directly to a complete facepiece. (2) The canister should provide a protection of 2 minutes against 1 per cent of phosgene, and 20–30 minutes against 0·1 per cent. The resistance should not exceed 3 in. of water. Protection of 10 minutes against 1 in 5×10^7 of diphenylchlorarsine or diphenylaminechlorarsine should be provided. The canister should be readily replaceable and should last for at least five years. (3) The facepiece, of rubber or leather, should be gastight, in not more than three sizes, and should incorporate eyepieces or a window. It should be simple in design, should interfere as little as possible with ordinary duties, should be suitable for mass production from materials available in Great Britain, and should last for at least five years. (4) The cost should be as low as possible. Let us equally bear in mind that industrial respirators and their possibilities are already familiar in chemical factories, and that any new advances will be of great interest in many peaceable occupations.

Direction Finding and Blind Flying for Civil Aviation

IT has been announced that the Directorate of Civil Aviation, Air Ministry, and the National Physical Laboratory, are co-operating in the study of problems relative to 'blind' flying as applied to air-line operation. The immediate necessities are three-fold, and the use of wireless transmission appears to offer the most likely means of their solution. They are: (1) The transmission of direction finding information over as long a range as possible, probably by short-wave radio. (2) Devices for warning the pilot of the proximity of obstructions such as high masts, or even other aircraft, in conditions of poor visibility. (3) The accurate guiding in and landing of aircraft when an aerodrome is obscured by fog, or in any similar conditions of reduced visibility. The Air Ministry is using a Vickers "Viastra", until recently the property of the Prince of Wales; it will be fitted with the necessary apparatus as soon as preliminary experiments have indicated the most promising type, and will be flown by Imperial Airways pilots. The aerodromes from which they will operate will probably be Croydon, Gatwick, and Gravesend. Imperial Airways will also be invited to send out signals at pre-arranged times, to the pilots of their normal machines, when over Africa and on the way to India and Australia, from which the reliability of different systems can be judged. A type of 'approach' beacon for blind landing, giving out a short aural note over a range of 20–25 miles, has already been ordered for experiment. If this is successful, the problem will then be to develop the use of a long-range direction finding system for use in conjunction with the short-range system, but without interfering with it.

Television in Great Britain Next Year

THE Postmaster-General has now authorised the B.B.C. to make arrangements with the Baird Television Co., Ltd., and the Marconi–E.M.I. Co., Ltd., for the provision of complete transmitting equipment for the operation of their respective systems at the Alexandra Palace, where constructional work has already begun. It is hoped that transmissions will start in the early part of next year, and will be followed as soon as practicable by a regular public service. As ultra-short waves will be transmitted, it will be possible to broadcast scenes in much greater detail than can be done to-day. Doubtless before very long many listening-in sets will be furnished with a television screen. In Germany, television is being pushed forward for political reasons; but in the United States although experimental television is an accomplished fact the business and advertising aspects of the new industry have to be carefully considered. In Great Britain luckily advertisement does not need to be considered, and the Government

dominates the whole position. The masts on the Alexandra palace will probably be about 600 ft. above sea-level, and there are few local obstructions. In the London area, it is understood that a wave-length of 6·6 m. will be employed for the visual and 7·2 m. for the sound broadcasts. As these rays are propagated in practically straight lines, their range does not extend much further than the visual horizon. The London area will be roughly a circle of radius 30 miles. There are some outstanding financial problems that have to be settled, such as the relative values of the televising and broadcasting rights of a prize fight. In the cinema industry, coloured pictures have greatly improved, so that it only needs stereoscopic projection to perfect them.

Effects of the 1934 Drought in the United States

IT was only to be expected that the American drought of 1934 would extend well into the growing season of 1935, in some parts of its extensive area, and this is proving to be the case. In a number of articles that have been issued by Science Service, Washington, D.C., during the past few months, the gradual contraction of the stricken area has been traced. In one such article, dated March 13, early spring rains in the Plains were mentioned, and a great excess from the Ohio Valley to the Gulf, sufficient to delay spring ploughing. On March 27 light rains were described as having eased the situation in the northern part of the western drought area; but dust storms were reported in the completely dry region in eastern Colorado and western Kansas and in Texas. On April 20 an improvement was noted in Texas and Oklahoma, and a hope on the part of the forecasters in the Weather Bureau that western Kansas and eastern Colorado might soon be relieved by invading depressions. Articles dated May 1 and 2 showed that this hope had not been fulfilled, the area in question remaining to represent the temporary "Great American Desert". A faint sprinkle of rain was described as having evaporated as fast as it fell in Dodge City. In the relieved areas, the cold weather and sodden fields, and the resultant delay in farming work, were said to be accepted with complacency after the previous extremes of drought and heat.

DUST storms, leading to the loss of the cultivated surface soil, had become a commonplace occurrence in the United States before the drought had nearly reached its greatest extent, causing great inconvenience and material damage to the States lying to the eastward of the driest region, as well as to western farmers. The drought itself is held, however, to be only partly responsible, as the dry soil would not have been blown away had the Plains not largely been deprived of their former permanent grass covering, of which the roots would have bound the soil in place through even the worst periods of deficient rainfall. Another article describes one of the processes whereby the drift of loose soil has been to some extent countered. This process, known to farmers as 'listing', consists of specially deep ploughing with the aid of motor-driven tractors. A special plough is used, which throws the soil on both sides; the furrows may be as many as fifteen feet apart, and are driven at right angles to the prevailing winds, which are generally from the north-west. Where the soil is heavy the tops of the ridges are covered with something more coherent than the normal surface tilth, and this partly accounts for the efficacy of the method, which, however, is due mainly to the fact that as the loose soil begins to move under the action of the wind, it tends to fall into the furrows and to be trapped in them. It is stated that the Soil Erosion Service does not regard this 'listing' as a solution of the problem of wind-erosion, the real solution being to restore the permanent grass, much of which was ploughed up during the War so that cereals could be grown.

List of British Vetebrates

FEW naturalists have at hand complete lists of the various groups of British vertebrata, and yet in the absence of such lists reference and checking often become unutterably tedious. The suggestion of the Association of British Zoologists that a complete check list of all British vertebrates should be compiled was, therefore, a sound proposal, and the list as it now appears will prove of value in many ways, especially to workers of wide interests. This is clearly due to the way in which the British Museum (Natural History) has applied itself to carrying out the suggestion, for apart from the Bird list (by B. W. Tucker) the work of compilation has fallen upon the Museum staff, and for the editing and publication it also has been responsible (pp. 66, price 1*s*.). The list is a check list and no more, giving the Latin and English names of species and often indicating by letter symbols something about the status. In contrasting this check list with the lists of other countries, one's first impression is that it is a short list, representing a land fauna not outstandingly rich in variety, and a second strong impression is that, much less than other countries, Britain has been subjected to the successful introduction of foreign animals. To the short list of animals marked as introduced should be added, amongst the mammals, the rabbit, the black rat and the brown rat, and the Japanese deer, *Cervus sika*, which is very much at home in part of the western highlands of Scotland and was introduced so long ago as 1887; amongst the birds, several species of pheasant, for *Phiasianus colchicus* is now a rare species in the coverts, its place having been usurped mainly by *P. torquatus*.

Traffic-actuated Road Signals

IN a paper read before the Institution of Railway Signal Engineers by F. Edwards, an abstract of which appears in *Roads and Road Construction* for July 1, the development of systems of road signalling is described. There are two main developments which may be regarded as milestones in the progress of street traffic signalling. The first system is time-controlled and, thanks to the specification issued by the British Standards Institution, it works fairly well. Up to the end of February of this year, grants had been issued for the erection of signals at more than

1,700 crossings in Britain, and naturally the installation of all these crossings is costly. The second step in advance was the introduction of the vehicle-actuated method of control, which has several advantages over the time-controlled system. With the time-controlled apparatus the 'right of way' is given to each of two or more intersecting roads for definite periods of time in sequence, quite regardless of the relative volume of traffic on the roads at any particular moment. One of the essentials of any form of control is to keep traffic moving, and this should only be subordinate to safety. The time-controlled system is powerless to differentiate between the volumes of the flow of traffic in the various directions. Many attempts were made in the past to produce a system which would provide maximum traffic facilities with maximum safety. There are now two systems of vehicle-activated control in practice, called the electromatic and the autoflex respectively. In the former, a vehicle passing over a pad makes contact and completes an electric circuit; in the latter the air in a channel in a rubber moulding is compressed and the compressed air produces the contact. The problem of co-ordinating a series of crossings is now being satisfactorily solved. Oxford Street, London, from Marble Arch to Tottenham Court Road is a good example of the advantages of this kind of control.

Invention of the Venturi Meter

In connexion with an article on "Early Hydraulic Engineering", in which the work of Clemens Herschel (1842–1930) is referred to, *Engineering* in its issue for August 2 reproduces a letter from Herschel to the late Dr. Unwin describing his invention of the Venturi Meter. The letter is dated June 5, 1888, and addressed from the hydraulic engineer's office of the Holyoke Water Power Co., Mass. In his letter, Herschel says he tested a one-inch Venturi Meter, under 210 ft. head: "I am now satisfied that here is a new and pregnant principle to be applied to the art of gauging fluids, inclusive of fluids such as compressed air, illuminating or fuel gases, steam, etc. Further, that the shape of the meter should be trumpet-shaped in both directions; such a meter will measure volumes flowing in either direction, which in certain localities becomes a useful attribute. . . . And we are but in the beginning of the art of measuring pressures, and differences of pressure. When these shall be delicately measured, the Venturi Meter will have become as delicate in its lower limits of capacity, as any other and it is on this score *alone*, that it is as yet inferior to some of the volumetric meters." The letter was found among the papers placed at the disposal of the Unwin Memorial Committee by Miss Unwin.

Electric Welding in Industry

The American Welding Society has awarded the S. W. Miller Medal to J. C. Lincoln, the founder of the Lincoln Electric Company, as the first to apply the electrical arc to building construction, and for his improvements in the art of arc welding. Mr. Lincoln has pointed out that by arc welding the cost of the repairs of machines has been greatly reduced. It has eliminated the noise of the riveting hammer in building construction. A joint made by arc welding is often stronger than the parent metal; while a joint made by riveting never is. The amount of the material needed for the structure is therefore considerably reduced. It is of particular importance in marine construction, where the smooth outline rendered possible by welding appreciably increases the speed of the ship. The most widely used application of all is the replacement of steel and iron castings by welded structural steel. This application gives a method of having a lighter, stronger and cheaper material than it is possible to get by casting. Already about one and a half million tons of castings a year have been eliminated by this method. Mr. Lincoln thinks that welding will entirely eliminate the rivet as a method of joining structures. It will also largely increase the value of worn and broken parts.

Industrial Physicists

The *Review of Scientific Instruments* reproduces in its issue of February the conclusions of the Conference held in New York to consider "the place of physics in industry and the best methods by which that place can be fully occupied". The Conference demands a training which shall develop: (1) a broad knowledge of the principles of physics with a leaning towards classical physics; (2) an intimate working knowledge of the more elementary branches of mathematics; (3) a grounding in the principles of chemistry sufficient for physical research; (4) power of expression in technical and especially non-technical language; (5) realisation that a research worker in industry is justified only by his value to the industry. It would be of great interest to discover whether these are the demands of industry in Great Britain, and if so, whether the training required is being provided by our educational methods.

Institute of Plant Industry, U.S.S.R.

A list of the publications during 1933 of the Institute of Plant Industry, Leningrad, compiled by Strumillo, appears as Bibliographical Contributions No. 4 of the Institute. The list of publications of this Institute, and of the old Bureau of Applied Botany which preceded it, is thus now complete from 1908 to the end of 1933. It covers 57 publications, is published in Russian and English, and the titles of all contributions of every volume are given in English even in cases where the originals contain no English summary. Most of the Institute's publications of specialised character have English summaries; those publications in this list which are not provided with one are indicated. The *Bulletin of Applied Botany, of Genetics and Plant Breeding*, together with its supplements, occupies the major portion of this list. The remainder is occupied by non-serial publications and by publications originating from the Institute, but issued by other publishers. "Plant Industry in the U.S.S.R." and "Agricultural Turkey" are two important contributions in the latter category.

Indexes arranged according to subjects and to authors are provided. The importance of the work of the Institute of Plant Industry, the extent of its activities, and the diversity of its serial and non-serial publications, make its bibliographical publications indispensable to applied botanists.

Ocean Transportation of Petroleum in Bulk

OWING to world trade depression and to production problems within the industry, there is now actually available excess oil tanker tonnage over demand. Of the world's steam tanker tonnage 44 per cent is, however, more than fifteen years old, consequently new tankers will shortly have to be constructed to replace these and to meet anticipated increase in demand when trade recovers. Mr. R. F. Hand read a paper on April 5 before the North East Coast Institution of Engineers and Shipbuilders, in which he indicated some of the problems attendant on ocean transportation of petroleum in bulk. Great care must be exercised in allocating vessels for specific work, account being taken of condition, size, position and capability of the tanker to carry the cargo in question. Freights cannot be imposed on a basis of cost plus a reasonable margin of profit, but must be fixed at a rate which the traffic can bear. Ultimate profit must be envisaged over a number of years, and provision made for periods when goods may actually have to be carried at a loss. A classification is suggested for petroleum products from the point of view of marine transport and types of vessel most suitable for carrying the various grades indicated. Operating costs are difficult to assess at the present time owing to the complex foreign exchange situation; but such data as are available prove that though the motor tanker is more economical for long hauls it is not always so in the case of short hauls.

The Science Museum

ACCORDING to the Report of the Science Museum for the year 1934 (London: H.M. Stationery Office, 1935, 1*s*. net) well over a million visitors have made use of the Museum, including more than a thousand organised groups and parties of about thirty, and the attendances at lectures were well over 30,000. The policy of holding special exhibitions to illustrate the advance of science into industry has been most successful, and the attendance at those on refrigeration from April until September 1934 and on rubber from November 1934 until April 1935 was very gratifying. The children's gallery has been visited by 13,000 children in school parties, and the introductory collection installed there has proved very attractive. Short accounts are given in the Report of the progress in each of the five divisions: industrial machinery and manufactures, mechanical and civil engineering, air and water transport, mathematics, astronomy and chemistry, physics and geophysics, and it is quite evident that the delay in reconstructing the central block is a serious obstacle in the way of a more instructive display of the material now crowded into inadequate cases. The Science Library now possesses a quarter of a million books, and nearly 50,000 readers have made use of them. The free space for new books is nearly exhausted and temporary housing will have to be provided until the central block becomes available.

Fuel Research Institute of South Africa

DR. J. G. VOGEL, director of the Fuel Research Institute of South Africa, has recently described the activities of the Institute (*S. African J. Sci.*, **31**, 194–209, Nov. 1934). Initially, the Union Government wished to encourage the export trade in coal, and prevent the damaging effect on the export of coal of unreliable grade. Now all coal loaded for export or bunkers must be graded by the Institute before shipment. The programme is determined by the fact that the coal industry is neither very old nor extensive, and the information available is limited. A first step is therefore a chemical survey. Already the Institute has made a notable contribution to the difficult problem of coal sampling by devising a novel sampling device. It consists essentially of a rotary drill working inside a sheath, up which a rapid current of air passes. The air and the coal abraded by the drill are drawn into a container after the manner of a vacuum cleaner, where the solids are retained. This apparatus not only enables samples to be collected from seams, but also from waggons—a problem which has not hitherto received a satisfactory solution. The Institute is equipped for research in coal chemistry and coal processing, and also for the study of liquid and gaseous fuels.

Census Statistics

THE normal series of publications dealing with the figures of the 1931 census is completed by the issue of General Tables, a volume of some two hundred and fifty pages (London: H.M.S.O. 11*s*.). It contains tables giving the populations by sex of the constituent regions of England and Wales—counties, boroughs, urban and rural districts—showing the changes that have occurred in recent intercensal periods. It also gives an analysis of the age and marital condition of the population at successive censuses during the last ninety years. Particulars are given of the birth-places and nationalities of the population in regions, boroughs and other urban areas, and comparative figures for England and Wales at successive censuses. There are also figures of population speaking the Welsh language. Much of the information given in the volume has hitherto been obtainable only by laborious extraction from separate county records.

The Imperial Institute

WE have received the annual report of the Imperial Institute, recently presented by the director, Sir Harry A. F. Lindsay, to the Board of Governors (London: Imperial Institute, 2*s*.). This gives a general account of the activities of the Institute and details of many special investigations which have been made with Empire products. These comprise work on silk, cordage fibres, tung oil, shellac, hides and leather, oil seeds, tanning materials, drugs and insecticides,

and the analyses and investigations of various minerals. The report directs attention to the wide range of valuable minerals produced in the Union of South Africa. The use made by the public of the exhibition galleries, and the provisions made for educational purposes are dealt with in the report, which indicates clearly the very useful purposes served by the Imperial Institute.

The Italian Seismological Society

THIS well-known Society has now existed for forty years, and the first number of the new volume of the *Bollettino* (33, 10–21; 1935) contains a brief survey of its history by the present secretary, Prof. G. Agamennone. The study of earthquakes as a whole in Italy may be said to have begun in 1870 with the works of Bertelli and De Rossi; but the issue of the *Bullettino del Vulcanismo Italiano*, founded by the latter in 1874, was declining after twenty years. The Italian Society, in imitation of its Japanese predecessor, was founded in 1895 under the direction of Prof. P. Tacchini, the director of the Central Office of Meteorology and Geodynamics, and continued ten years later under that of his successor Prof. L. Palazzo, the present president being Prof. G. Cicconetti. The activity of the Society may be judged from the volumes of the *Bollettino* so far published, which contain nearly 500 papers occupying more than 9,000 pages.

Cambridge Microtomes

THIS year the Cambridge rocking microtome, one of the most familiar instruments in biological laboratories, attains its jubilee. The Cambridge Scientific Instrument Co., Ltd., has issued a new folder, illustrating this instrument and also a more heavily built and modified form of it for cutting flat sections of larger objects. The folder shows in addition a massively built sliding microtome, the design of which was completely overhauled two years ago, which cuts large sections, 60 mm. × 60 mm., in either paraffin or celloidin, and a freezing microtome of new design. Hints on the care and sharpening of microtome knives are added.

International Society of Leather Trades' Chemists

THE bi-annual conference of the International Society of Leather Trades' Chemists, in conjunction with that of the Internationalen Vereins der Leder Industrie Chemiker, will be held on September 1–6 at the Institut des Arts et Metiers, 50 Boulevard de l'Abattoir, Brussels, Belgium. The reception of members and visitors will take place on Sunday evening, September 1, at 8 p.m., at the Palace Hotel, Place Rogier, while the official banquet, at which the Burgomaster of Brussels will be present, together with other representatives of civic, commercial and scientific bodies, is fixed for Wednesday, September 4. Some thirty papers are to be read and discussed. Further details can be obtained from M. A. Fievez, 7 rue d'Audiger, Soignies, Belgium, or from the Honorary General Secretary of the I.S.L.T.C., 17 Market Street, London, S.E.1.

Announcements

PROF. J. A. NIXON and Dr. R. E. Lane have been appointed to fill vacancies in the membership of the Industrial Health Research Board.

THE following appointments have recently been made by the Secretary of State for the Colonies: Mr. A. W. Gledhill, to be veterinary officer, Uganda; Mr. R. M. Davies, district agricultural officer, Tanganyiki, to be senior agricultural officer; Mr. S. P. Teare, game ranger, Tanganyika, to be game warden.

THE Managers of the Royal Institution have awarded the Dewar research fellowship to Mr. A. R. Ubbelohde, formerly Senior Scholar of Christ Church, Oxford, and at present holder of a senior research award of the Department of Scientific and Industrial Research. Mr. Ubbelohde will take up his new appointment in the autumn. His researches have been largely in physical chemistry, and it is expected that his experience will be valuable in connexion with the researches directed by Sir William Bragg at the Royal Institution on the structure of matter.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

Scientific Officers (Ref. A. 764), junior scientific officers (Ref. A. 765), and assistants, grades I–III (Ref. A. 766–8) at the Royal Aircraft Establishment, South Farnborough, Hants—The Chief Superintendent (Aug. 17).

An assistant signals officer and a signals officer in the Signals Branch, Air Ministry—The Secretary (S 1, Room 436), Air Ministry, Adastral House, Kingsway, W.C.2 (Aug. 19).

A senior lecturer in the Department of Pure and Applied Science, Loughborough College—The Registrar (Aug. 24).

An engineer officer in the Public Works Department, Buildings and Roads Branch, Punjab—The High Commissioner for India, General Department, India House, Aldwych, London, W.C.2 (Aug. 26).

An assistant lecturer in the Department of Zoology, University of Leeds—The Registrar (Aug. 31).

An assistant lecturer in the Department of Physiology, University College of South Wales and Monmouthshire—The Registrar (Aug. 31).

A lecturer in morbid anatomy in the Department of Pathology, University of Aberdeen—The Secretary (Sept. 15).

A professor of mathematics in the University of Aberdeen—The Secretary (Sept. 30).

Temporary architectural and engineering assistants in the Directorate of Works and Buildings, Air Ministry, and at various aerodromes in the United Kingdom—The Secretary (W.B.9, Room 161), Air Ministry, Adastral House, Kingsway, W.C.2.

Temporary assistant mechanical and electrical engineers—The Secretary, Air Ministry (W.B.9), Adastral House, Kingsway, London, W.C.2.

A lecturer in geography and mathematics at St. Hild's College, Durham (Diocesan Training College for Women)—The Principal.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 264.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Beta Processes and Nuclear Stability

1. IT is well known that the stability of the atomic structure is closely connected with the mechanical conservation laws. It has been shown that even the stability of the atomic nucleus, in particular the nuclear beta stability, is subject to conditions which can at least formally be interpreted as conservation laws for the mechanical integrals of motion[1]. It may be pointed out, however, that the application of the usual mechanical conservation laws only is not sufficient to account for nuclear stability.

If one assumes a coupling of the nucleus with the electron field, the mechanical conservation laws alone would not exclude transitions in which a nucleus emits two electrons simultaneously and thus changes its charge by two units. This process would not involve the occurrence of a so-called neutrino, and we should expect considerable transition probabilities for such transformations. The radioactive transformations, however, show no indication of this type of double processes. RaD, for example, emits only a single electron, a second electron being afterwards emitted by the product nucleus, RaE. We have to conclude from this fact that the simultaneous emission of two electrons is a higher order transition of very small probability, involving the simultaneous occurrence of two 'neutrinos'.

The question arises why the neutrino occurs even if the mechanical conservation laws do not require such a particle. We are led to conclude that the beta-transitions are subject to an additional condition. The simplest form in which such a condition can be expressed seems to be the following: "Any production of particles has to involve the simultaneous production of an equal number of antiparticles". Attributing a positive sign to particles, a negative sign to antiparticles, the above condition can be regarded as a conservation law for the total number of particles. In the case of the natural beta decay this rule can be easily satisfied if one calls the hypothetical second particle an 'antineutrino'.

So long as we confine our attention merely to the production of pairs of differently charged electrons, the conservation of the total number of particles is secured by the conservation of charge and thus does not require the introduction of any special assumption. Any theory of the beta decay using the concept of a neutrino has to abandon this connexion and has to introduce an additional condition beside the conservation of charge.

2. It has been suggested by several authors that the interaction between nuclear particles might be due to beta processes of higher order. The small probabilities of the beta transformations, however, make it extremely difficult to account for the actual order of the nuclear interaction. Prof. Lauritsen and Prof. Oppenheimer have kindly pointed out to me that the possibility of very high beta decay probabilities for high decay energies is incompatible with recent investigations on the beta decay of Li^8 and B^{12} and that therefore the beta decay must be due to an extremely weak coupling energy. This fact is very likely connected with the occurrence of the so-called neutrino.

I should like to point out here that it seems to be inconsequential to connect the nuclear interaction with the natural beta decay so long as there is no necessity to assume a neutrino to be involved in nuclear binding. We have to expect that the coupling between a nucleus and the electron field is very much stronger than the interaction with what is called a neutrino. It is only due to the restrictions implied by the conservation laws discussed above that the coupling between nucleus and electron field does not become effective in the natural beta decay. If we proceed, however, to higher order processes such as are involved in the above considerations on nuclear binding, these restrictions do not hold any longer and the weak coupling with the neutrino can be entirely neglected in comparison with the production of electron pairs. It may be found difficult, however, to reconcile even the known facts on the production of pairs and on the small isotope shift observed in spectral lines with the strong nuclear binding forces.

Beta Ray Spectra of Artificially Produced Radioactive Elements

WE have investigated a series of β-ray spectra emitted by radioactive elements obtained by neutron bombardment. The results of the measurements together with those previously published by us in NATURE are given in the accompanying table.

Atomic No.	Element	Half-life period (τ)	Max. energy (in kv.)	$\tau.F(\eta_0)$
7	N	11 m.	1,400	58
13	Al	2·3 m.	3,000	340
15	P	3·2 m.	3,600	1,400
15	P*	14 d.	2,050	630,000
25	Mn*	2·5 h.	3,200	50,000
35	Br*	18 m.	2,000	480
35	Br*	4·2 h.	2,050	15,000
35	Br*	36 h.	950	5,900
45	Rh	44 s.	2,600	170
45	Rh	3·9 m.	2,100 ?	420
47	Ag	22 s.	2,800	130
53	I*	25 m.	2,100	3,700
79	Au	2·7 d.	1,100	17,000
77	Ir	19 h.	2,200	585,000

Substances marked with an asterisk were separated by chemical methods analogous to those used by Szilard and Chalmers[1]. The radioactive manganese was separated from a solution of potassium permanganate, the radioactive P^{32} from carbon disulphide.

We tried to relate our results to Fermi's theory of β-ray decay. For this purpose it is necessary to calculate for each radioactive element Fermi's[2] function $F(\eta_0)$, where $\eta_0 = H\rho_{max.}/1700$. According to Fermi, the values of $\tau.F(\eta_0)$ should be distributed in two groups, differing from each other by a factor of about 100. The first group should correspond to allowed transitions, the second to the forbidden ones. As can be seen from the table, such a sharp separation into two distinct groups, as obtained by Fermi for natural β-active elements, can scarcely be found for the substances we investigated; also, the data obtained by us do not fit the well-known Sargent diagram.

Velocity of 'Slow Neutrons'

A NEUTRON source (beryllium and 300 millicurie radon) was placed in the centre of a block of paraffin wax, of about 20 cm. diameter in all dimensions. After emerging from the paraffin, the neutrons had to pass, on their way to the detecting apparatus, through the marginal parts of a wooden disc of 50 cm. diameter and 2 cm. thickness, which could be made to rotate with a speed of 4,000 rev. per minute. This speed corresponds to a velocity of about 9×10^3 cm./sec. of the parts of the wood through which the neutrons penetrated. From former experience one would expect each slow neutron, while passing through the disc, to suffer a number of collisions with the protons contained in the wood, and therefore the velocity of the disc would be superimposed on their velocity distribution with the disc at rest. Assuming that a large part of the neutrons have thermal velocities, which are for neutrons of the order of 2×10^5 cm./sec., an asymmetrical distribution of the directions of the neutrons emerging from the rotating disc would result, about ten per cent more slow neutrons being emitted in the direction of rotation than in the opposite direction.[1]

In order to get evidence of this asymmetry, we placed a cadmium screen with a hole of 6 cm. × 6 cm. near the rotating disc, defining thereby a region where the neutrons were allowed to emerge from the wood. Two boron-lined ionisation chambers were placed behind the screen in such a way that they collected the neutrons projected at less than 45° and 135° relative to the direction of motion, respectively. The chambers could in turn be connected to a linear amplifier and mechanical counter; and alternative countings of equal duration were made with the disc rotating alternately one way or the other.

The experiments revealed indeed an asymmetry of the expected order of magnitude. Adding together the counts of the chamber which lay in the direction of motion of the disc, we get 11,100 particles against 10,644 for the corresponding sum of the counts in the other chamber. The observed difference is, therefore, 4·2 per cent, with a probable error of one per cent. When comparing this value with the beforementioned theoretical value of 10 per cent, we must take into account that only part of the counts was really due to the action of slow neutrons. By screening off the slow neutrons by means of a cadmium plate, the number of counts was reduced to about one half; these remaining counts were probably partly due to fast neutrons, partly to the natural contamination of the chamber. The result of the experiment may, therefore, be taken as evidence that the main part of those neutrons which are strongly absorbed in cadmium have very nearly thermal velocities.

In conclusion, we would like to thank Prof. J. Franck for many stimulating discussions.

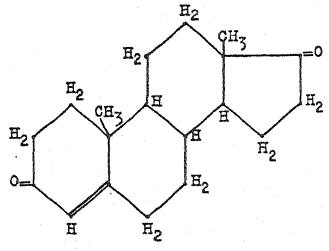
Activity of Androstendione on the Sexual Organs of the Male Rat

It has repeatedly been stated that the relation between the results of capon test and rat test varies with preparations having male hormone action[1,2]. A definite number of capon units, applied in the form of testicular extracts, has a stronger activity on the sexual organs of the male rat than pure androsterone or hormone fractions from male urine. Gallagher and Koch[2], moreover, showed that boiling alkali destroys the hormone action of testicular extracts only, but not of the urine extracts. In fact, androsterone and *trans*-dehydro-androsterone, the existence of which in the urine has been described by Butenandt, are not altered by treatment with alkali.

Recently, L. Ruzicka and A. Wettstein have prepared *trans*-dehydro-androsterone from cholesterol and transformed it by oxidation into androstendione of melting point 173°–174°. Like corpus luteum hormone, it is an unsaturated diketone, and has the following formula:



It is now well known that the boiling of corpus luteum extracts with alkali destroys the hormone action. L. Ruzicka and A. Wettstein therefore recently suggested that androstendione or analogous compounds might be responsible for the peculiar action of the testicular extracts.[3]

As Ruzicka and Wettstein have already reported, the capon unit for androstendione and likewise for the saturated androstandione amounts to about 100 γ, according to the 6-day test used in this

laboratory. These substances are therefore somewhat less active on the comb than androsterone (60 γ), and particularly the diol (15 γ) obtained by hydrogenation of androsterone. In the meantime, I have examined these and related compounds also on the young castrated male rat. The first experiments have already shown that androstendione influences the seminal vesicles much more strongly than androsterone. In the following table, the results of a further series of experiments are shown, daily doses of 50 γ, 100 γ and 200 γ of the different preparations having been administered :

	Capon unit	Weight of the seminal vesicles in mgm.			Weight of the penis in mgm.		
	γ	50γ	100γ	200γ	50γ	100γ	200γ
Androstendione	100	25	51	285	85	100	150
Androstandione	100	16	27	51	57	89	92
Androsterone	60	11	14	17	46	60	65
Diol	15	14	25	40	68	89	98
Diol-monoacetate	15–20	13	—	—	64	—	—
Diol-diacetate	15–20	13	—	—	60	—	—

The rats were castrated at a weight of 70–80 gm., and only used 4 weeks after the castration. They received the above-mentioned doses once daily for 20 days. On the twenty-first day the animals were killed and the seminal vesicles and penis weighed. The weights of these organs at the beginning of the experiment were about 6 mgm. and 50 mgm. respectively. Three to ten animals were used for each experiment.

The table clearly shows the high activity of androstendione on the seminal vesicles and the penis. The increase of weight of the seminal vesicles amounts, for example, with a dose of 50 γ to three times, with a dose of 100 γ to five times and with a dose of 200 γ to twenty-three times that of the androsterone animals. Also androstandione of m.p. 132° shows a considerable activity on the sexual organs of the rat, similar to that of the diol. In this connexion it must be remembered that A. Ogata and S. Hirano[4] report the isolation of an active substance of m.p. 129° from testicles, which may perhaps be identical with androstandione. The testosteron recently described by David, Dingemanse, Freud and Laqueur[5] of m.p. 154°–154·5° resembles more the diol in its activity. The fact that androstendione, even in the absence of the substance *X* postulated by Laqueur and his co-workers, and in spite of its rather moderate activity on the capon comb, influences the sexual organs of the young male rat to an extraordinary extent, gives further support to the hypothesis of L. Ruzicka and A. Wettstein that androstendione, or a similar unsaturated ketone like 3-keto-17-hydroxy androstene, may be identical with the less stable male hormone or hormones of the testis.

A Crystalline Fluorescent Dehydrogenation Product from Vitamin B_1

THE production of fluorescent solutions on oxidation of vitamin B_1 (antineurin) has been indicated in these columns by Peters[1], but no crystalline fluorescent product has hitherto been reported.

An alkaline solution of potassium ferricyanide transforms the vitamin hydrochloride ($C_{12}H_{18}ON_4SCl_2$) into a pale yellow, sulphur-containing compound (crystals m.p. 221°, from chloroform) having, in neutral or alkaline solution, an intense blue fluorescence ; it possesses all the recorded properties of the 'thiochrome' ($C_{12}H_{14}ON_4S$) of Kuhn and his colleagues[2], including a similar absorption spectrum. This result is to us the more interesting, as thermal decomposition of the vitamin also yields a blue fluorescent compound[3], $C_9H_{10}ON_4$, which may have a related constitution.

A New Alkaloid of Ergot

SOME years ago, Chassar Moir[1] demonstrated by clinical experiments that aqueous extracts of ergot, so far from being valueless as maintained by pharmacologists, contain an oxytocic principle with a remarkably rapid action on the human puerperal uterus. This principle was isolated by Dudley and Moir[2] and found to be a water soluble alkaloid, which they named ergometrine. During the process of manufacture of this alkaloid, we have isolated in addition a new alkaloid which is isomeric with ergometrine and convertible into it. The relationship is apparently similar to that existing between the alkaloidal pairs ergotoxine–ergotinine and ergotamine–ergotaminine. We have accordingly named it ergometrinine. In the above-mentioned pairs, one member in each case is comparatively inert. Whether the new alkaloid has the same clinical action as ergometrine or is a relatively inert isomeride remains a question for clinical investigation.

Ergometrinine has the formula $C_{19}H_{23}O_2N_3$. It is fairly soluble in chloroform and has $[\alpha]_{5461}^{20°} = +520°$ (in chloroform $c = 1$). It decomposes at about 195°. It forms a crystalline nitrate $B.HNO_3$, hydrobromide, B.HBr and an acid sulphate $B.H_2SO_4$. The salts are easily soluble in water and give dextrorotatory solutions.

It is of interest to recall that ergine[3], $C_{16}H_{17}ON_3$, a degradation product of the ergot alkaloids, has a high optical rotation, $[\alpha]_{5461}^{20°} = +598°$ (in chloroform $c = 1{\cdot}5$) similar to that of ergometrinine, and it seems probable that the latter has the same configuration.

Expansion of Films of Myosin on Potassium Lactate

BY suitable manipulation, it has been found possible to spread true monolayers of proteins on various substrates. These monolayers can be examined both in the Langmuir trough and by the method of surface potentials. In the course of an investigation on the properties of monolayers of myosin, it has been found that when this protein is spread on potassium lactate at *p*H 7, it assumes a much more expanded form than it does on potassium chloride and other neutral salts, at the same normality and *p*H. It is interesting to note that it is a hydroxy-acid which causes this expansion, as neither acetates nor propionates are effective; the extension is noted, although to a less degree, with tartrates.

Furthermore, on lactate, as the substrate increases in alkalinity, the film assumes an even more expanded form, whereas no such change is noticeable with potassium chloride. The effect seems to be specific in regard to myosin, for egg albumin shows no such difference.

In the accompanying table are given the approximate values for the area occupied by a gram of myosin on various substrates, and the phase boundary potential difference caused by the film.

*p*H	Substrate	ΔV max. (millivolts)	Area per gram (square metres) (1) At commencement of uniformity of the monolayer	(2) At the point of maximum phase boundary potential
7	*M*/2 Potassium chloride	275	525	310
7	*M*/2 Potassium lactate	160	1450	600
10	*M*/2 Potassium lactate	160	2200	1000
4	*M*/2 Potassium lactate	170	1300	250

These facts may be interpreted as indicating a tendency of the myosin to extend in the presence of lactate ions. The role allotted to lactic acid at the present time in the physiology of muscle is admittedly a subordinate one, but it is certainly interesting to find that the lactate ion and the contractile substance have this mutual relationship. If the lactate does take any active part in the cycle of events during contraction, it might conceivably be that of facilitating an active relaxation of the fibrils during recovery.

Molecular Orientation and the Probability of Dissociation of Molecules by Electron Impact

HYDROGEN when bombarded by electrons with energy greater than 27 e.v. dissociates according to the following scheme:

$$H_2 \rightarrow H_2^+ + e \rightarrow H + H^+ + e + \text{kin. energy}^1.$$

In such a case, the dependence of the probability of the process upon the molecular orientation toward the electron beam will be shown in the angular distribution of the dissociation products, for they fly apart swiftly (at a velocity of 7–11 volts) along the line in which the molecular axis lay at the moment of excitation; strictly, however, a small deviation caused by the translational and the rotational motion must be considered. Our recent measurement of this distribution shows conclusively that the probability increases rapidly as the molecular axis approaches, from the perpendicular position, that parallel to the electron beam.

In Fig. 1*a*, hydrogen molecules stream downward from the jet *A* to be bombarded by 86-volt electrons in a horizontal broad thin beam, so that the sheath of ionisation is sufficiently widespread over the hole *B*. Positive ions the direction of which is defined by the hole and the twin slits of the shield (Fig. 1*b*) are received by a Faraday cage maintained at − 112 volts against the shield. The receiving system can be rotated around the cylinder axis. As the arrangement is of such high cylindrical symmetry, any deviation from a circle of the polar diagram of the current flowing into the Faraday cage indicates the dependence of the probability of ionisation or dissociation upon the molecular orientation.

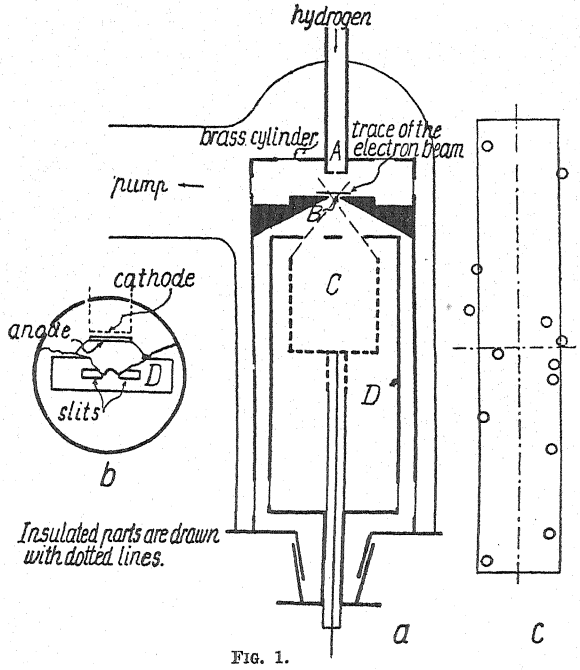

FIG. 1.

Fig. 1*c* shows the actual diagram obtained, its longer side being parallel to the electron beam. The electrostatic field due to the electron beam and ions[2] and the possible ionisation inside the shield by the scattered electrons with unequal angular distribution[3] are contrary or insufficient to produce the distortion of the diagram observed. Actually, an almost perfect circle was obtained with mercury vapour which filled the ionisation chamber uniformly. Molecular ions simultaneously formed will hit the part between the two slits of the shield. Another type of ionisation: $H_2 \rightarrow 2H^+ + 2e$, is much less frequent[1].

A similar investigation of the dissociation process through the state is in progress.

Influence of a Magnetic Field on the Viscosity of Para-Azoxyanisol

IT is known that a magnetic field has an influence on the orientation of the molecules in anisotropic liquids[1]. As it seems probable that the coefficient of viscosity of these substances will depend on whether, and in which direction, the molecules are orientated, a magnetic field may be expected to influence the value of the viscosity coefficient. The first experiments on this subject were made by M. W. Neufeld[2], who investigated the influence of a magnetic field on the velocity of flow of anisotropic liquids (*p*-azoxyanisol and anizaldazin) through a capillary tube. But, as is well known, in a layer of anisotropic liquid so thin as that in the capillaries used by Neufeld (diameter 0·09 mm.), the action of the field may be impeded by the directive action of the walls. Consequently, Neufeld's experiments cannot be regarded as definitive.

In order to examine the question further, I applied a method in which thicker layers of liquid were in motion, and the surface of friction was a plane, so that it was possible to introduce a magnetic field perpendicular to this plane. This method is somewhat similar to that used by Quincke[3] for measurements of the influence of an electric field on the viscosity of liquids.

On one side of the beam of an analytical balance, a glass plate, 48 mm. × 24 mm. × 0·8 mm., was hung in a vertical plane. The plate was immersed in the liquid under investigation, the liquid being in a vessel having two parallel walls 6 mm. apart. The vessel was placed in a thermostat between the poles of an electro-magnet. Thus the plate could oscillate vertically in its own plane. The period of the oscillations was about 5 sec.; the maximum amplitude was 0·5 cm. The damping of such oscillations depends upon the viscosity of the liquid in which the plate is immersed. So far, the influence of the density of the liquid on the damping has been neglected. The apparatus was calibrated with sugar solutions, and then the measurements with *p*-azoxyanisol were made. Its temperature was 125° C. (anisotropic-liquid phase). The damping of the oscillations of the plate was measured without and with the magnetic field (2,400 gauss) perpendicular to the plate. The experiments have shown a rather unexpectedly great influence of the magnetic field on damping. From the values of the logarithmic decrements, the viscosity coefficients were determined, and it has been found that the viscosity in the magnetic field is about 3·5 times greater than without the field. This effect disappears completely after the transition to the isotropic-liquid phase (at a temperature of 135° C).

The experiments are being continued in order to examine how far this effect depends on temperature as well as on the direction of magnetic field. Other substances in their anisotropic-liquid phase are now also under investigation, and the results will be published shortly.

I wish to express my best thanks to Prof. M. Jeżewski for his helpful interest in these experiments.

Philosophy and Modern Science

WHEN Dr. Dawes Hicks wrote in his first letter[1] of "that which is sensed", I could not be sure whether he meant an external object, a light wave, or a Russellian sense-datum; but it appears from his further letter[2] that he meant none of them, but something much more like what I call a sensation. The patch of colour and my awareness of it seem to me to form an inseparable whole; I cannot imagine either without the other, and in any event it is only sensations which we are aware of that can form any basis of knowledge, and therefore that are relevant for my purpose. I do not deny the mental component in a sensation, but I do say that the recognition of physical and mental components in its structure is the result of inference and not a direct observation. Of course I agree fully that discrimination and comparison follow immediately on sensation; their nature is what I am trying to elucidate.

The word "universals" was not introduced by me, but by Dr. Hicks in a definition of "concept" that I do not accept; and the statement that numbers are not existents implies a restriction on the meaning of "existence", about the utility of which there might be a good deal of argument. In Dr. Hicks's sense I am prepared to admit that Neptune may be neither a universal nor a concept; but that does not affect the fact that it is a concept in mine. I never said that an object was a generalisation or an idea of a class of objects; it is a term in a general law or laws that serve to summarise and predict sensations, and such a term is what I have called a concept. I am certainly not the first to use the word in that sense, and I know no other in common use that would express the same meaning.

Perhaps I should explain again that I am not discussing the correctness of any opinion about the nature of the external world or of the mind. I am discussing the nature of the foundations of empirical knowledge, including inference. My objection to most of the theories of science propounded both by physicists and by philosophers is that they postulate from the start a degree of knowledge that cannot possibly be primitive; they begin at the middle or the end instead of the beginning, and thereby fail to come to grips with the fundamental problems.

Phonemes

AT the recent International Congress of Phonetic Sciences, many of the papers contained discussions of 'phonemes' and 'phonology'. There were nearly as many definitions of a phoneme as there were papers, and nobody seemed to have any clear idea of what was meant by the term. The hope was expressed that perhaps the psychologists might be able to discover what a phoneme is. At the Congress dinner, one speaker compared the hunting of the phoneme to the hunting of the snark—with the difference that at least there was a snark. Apparently the phoneme was smiled out of existence. This, however, was not the fault of the phoneme, but of the hunters who failed to find it. The nature of language shows that phonemes do exist, and the successful study of language requires that they shall be found.

Abandoning all speculations concerning what we think we hear and concerning what printed words may be supposed to indicate, we approach the problem as if we had been born deaf and had never learned to read. We first make a collection of tracks of speech on sound films. One after another we find stretches of vibration of more or less homogeneous character. Each one of them was produced by an impulse of the speaker. Such an impulse we term a *speech sound*. The record we have before our eyes is the expression of such speech sounds and it is the only information we have about them. On comparing the records we find that groups of similar speech sounds can be formed. In this way we establish that spoken language consists of a succession of speech sounds, more or less overlapped, and that these speech sounds can be grouped on the principle of similarity. A term is needed to indicate any one of the speech sounds of a group; for this we use the word *phoneme*. A phoneme is not an average of speech sounds; it is one of a group of similar sounds without specification of which one it is. Such a sound can be indicated by a letter. In this way we get a phonetic alphabet that correctly represents spoken language.

Though deaf and unable to read, we can find the phonemes and are able to express them in numbers obtained by measurement. The same procedure might be useful in regard to other problems of language.

Fibre-Forms in Animal Hairs

THE effect of steam on the fibre-forms of white fox guard hairs reported by Dr. R. O. Hall[1] appears to be an example of a phenomenon, of very general occurrence in wool fibres, which has been described by me in connexion with fibre-forms in merino wool[2]. In the fleece this wool has a waviness which is, to a first approximation, sinusoidal, but the wave form is not entirely stable at ordinary humidities in single fibres withdrawn from the locks, so that in the natural state the fibres must be in a condition of strain, engendered, it may be, during the passage of the potentially curly fibre up the shaft of the follicle, or perhaps due merely to the closeness of packing of the fibres in the locks. The change in the form of a single fibre which proceeds slowly at room humidity is greatly accelerated when the fibre is wetted; it is an elastic deformation, and not a swelling phenomenon, since it is irreversible, and it may be resolved into torsional and flexural changes of which the former are more important. The obvious interpretation of the effect is that in the fleece the fibres have 'cohesive set' which is not relieved naturally because the closeness of packing and greasiness of the fibres in the locks preclude any readjustment under the action of atmospheric moisture.

After reaching an equilibrium form in cold water vapour, the fibre may change its configuration still more if the temperature is raised, and this final change may be compared with the effect obtained by Hall. In view of the fact that the merino wool fibres have existed in a state of strain in the presence of an alkali (the 'suint') the most natural explanation of the temperature changes is that in the fleece the fibres have not only 'cohesive' but also 'temporary' set[3,4], this being stable in cold water but not in hot water or steam. It will be seen that this is also a possible explanation of the flexural changes in steamed fox hairs; in them, of course, any cohesive set would be relieved naturally, since the hairs in the pelt are relatively free from mutual impedance. From this point of view Hall's highly curled hairs are in their normal, unstrained configurations, whilst the fibres in the pelt are temporarily set in straighter forms.

It may be, although this does not seem very probable, that any flexural changes occurring in steamed hairs are due to differential super-contraction following strain in the presence of an alkali; differential super-contraction would also be effective if, as is conceivable, there are structural faults of such a nature that the keratin on one side of the fibre is deficient in those lateral linkages which are responsible for the stability of normal α-keratin in steam. 'Weathering', therefore, must only be regarded as one of a number of possibilities.

The interpretation of effects of this kind is of considerable importance biologically, since the study of fibre-forms can only lead to a knowledge of the mechanism of growth if those factors acting after keratinisation is complete have been taken into account. Whether the cause of Hall's effect is really 'weathering' is, therefore, worth determining; tests on fibres from the pelts of very young foxes would probably throw light on the question.

Effect of Pressure of Atmosphere on Development of Red Clover

SINCE 1932, studies in this laboratory have investigated the effect of partial pressures of various gases on the nitrogen fixation process in inoculated leguminous plants. The results, which throw considerable light on certain properties of the mechanism employed in this biological process, will be reported in detail in a future publication. In connexion with this research, observations which may be of general interest were made on the effect of growing clover under a fairly wide range of atmospheric pressures. Little work appears to have been reported on this aspect of plant physiology; discussion of the effect of gas pressures in most texts is restricted to the effect of partial pressures of oxygen and carbon dioxide in short-time experiments.

In these studies, red clover plants were grown from two to three months in 10 litre pyrex serum bottles on a sand substrate provided with the required plant nutrients (Crone's solution) and kept under pressures ranging from 0·12 to 1·8 atmospheres. Each bottle was provided with a mercury manometer (with trap) to measure the desired pressure; carbon dioxide was added as required by a method previously described[1]. Three times a week all bottles were aerated for 30 minutes and the pressures adjusted, thus preventing an accumulation of oxygen from the carbon dioxide decomposed in photosynthesis.

The most surprising feature of the study was the relatively good growth made by the plants over the entire range of pressures used; differences were noted, but in general, all plants developed even at the extremes of pressure. At pressures greater than atmospheric, nitrogen gas was used to increase the total pressure; the growth of the plants appeared to be quite normal and indistinguishable from plants grown in air. At pressures less than atmospheric and greater than 0·20 atm., a definite stimulation of plant development was noted. The leaves were larger and broader and the plants were slightly greater in size (dry weight) than the control plants kept at normal pressure.

Pressures below 0·20 atm. usually caused some inhibition of growth, probably due to low pressures of oxygen. Previous studies of the effect of pO_2 indicated that plants kept in atmospheres in which the pO_2 becomes less than 0·05 atm. develop typical signs of carbohydrate excess, namely, red stems, yellow leaves and stalky growth habit. Root development under these conditions is characterised by tuberisation. Responses similar to these were observed in plants grown under low total pressure and hence low pressure of oxygen.

Occasionally freak growths were encountered in plants grown under low pressures, including false nodules on the roots, long and pointed leaves and, more rarely, four and five leaves instead of the usual three. Similar studies with other species might be of value in interpretation of types of plant growth at different altitudes.

Celluloid Tubes for Sampling Cores of Deep Sea Mud

IN recent years, there has been considerable progress in obtaining long cores of deep sea mud in the course of oceanographical and limnological work. Analysis of the stratification of these cores frequently gives valuable geological, geochronological and palæoclimatological results. During deep sea investigations it is possible—at least in the U.S.S.R.—to secure cores four to five metres in length. The preservation and subsequent examination of these cores present, however, some difficulties, due to the necessity of pushing out the obtained core from the Ekman tube, the *Meteor* type of sounding tube, and the glass container. This operation is often followed by the secondary deformation of the core, and includes other difficulties of minor importance.

The use of glass containers permits the cores obtained to be kept for a long time in a humid and undisturbed condition. Recently it has been found practicable to remove the cores from metallic tubes in such containers on board ship (Dr. Kuenen[1] on board the *Willebrord Snellius*). This may be ascribed to the fact that the glass container, being placed inside the Ekman or the *Meteor* type tubes, narrows the opening of such a tube, and consequently the length of core is considerably diminished. Dr. Kuenen's method, however, causes the deformation to be greater, and even doubled.

Instead of glass containers we have used brass ones, with thin walls, that have been placed in tubes of the *Meteor* type or simply adjusted to their stopper. They are not transparent, however, and in using them the process of subsequent withdrawing of cores for their further examination is quite unavoidable. Glass containers, in spite of their transparency and non-oxidisability, have necessarily thick walls and are very fragile and heavy.

In connexion with these difficulties, I venture to suggest that celluloid or some other transparent plastic material be used for the preparation of containers to secure deep sea mud. These containers could have very thin walls (0·2–0·3 mm. or less) and would possess many following advantages: they would be cheap, light, transparent and chemically inactive; moreover, the core could be withdrawn by cutting the container along its length. The thin walls of the suggested containers would make it possible to use them inside the Ekman or *Meteor* type tubes without diminishing the size of the openings. The core included in such a container could be divided into vertical or horizontal sections, even without having to be withdrawn from the container.

Symbiotic Association between Flies and Nematodes in Galls of Eucalyptus Trees

GALLING of the flower buds of certain trees in Australia, notably *Eucalyptus rostrata* and *E. hemiphloia*, is sometimes so heavy that no flowers appear, and no honey harvest is reaped. The chief causes of galling are agromyzid flies of the genus *Fergusonina*, Malloch.

Inside the galls the fly larvæ are associated with small nematodes, which I have placed in a sub-genus of the plant-parasitic genus *Anguillulina*. The nematodes live in the gall-cavity in contact with the fly larvæ, and ultimately a number of fertilised females enter the body-cavity of the female larvæ of the fly. There eggs are laid, and when the female fly in turn deposits its eggs in young flower buds a number of larval nematodes accompany them. The nematodes at once feed on the plant tissues and give rise to proliferating cells on which the fly larvæ feed, making hollows in which they are associated with the worms.

The symbiosis appears to have arisen as an accidental association between agromyzid leaf-tunnelling larvæ and plant parasitic nematodes.

Goodey[1] has described a parasitic association between the frit-fly of oats and a nematode, which may correspond to one of the steps in the evolutionary series which led to the highly organised association outlined above.

Absorption Spectrum of Methyl Iodide

THE excited state or states, designated by Mulliken as $^{1,3}E$, that are concerned in the ultra-violet absorption continuum of methyl iodide, have been compared with the $^{1,3}\Pi$ states of the ICl molecule[1]. The absence of a band system accompanying the continuum has led to the assumption that the upper state is unstable, whereas a comparison with the $^{3}\Pi$ states of I_2, IBr and ICl suggests that a ^{3}E state of CH_3I might possibly have a potential curve with a shallow minimum, and that there might exist a band system the convergence limit of which would occur at a wave-length much longer than that of the absorption maximum near λ 2600. The discovery of such a convergence limit would have the additional interest of providing an accurate value of the energy of the C–I bond.

To test this possibility, the absorption spectrum of gaseous methyl iodide at 220 mm. pressure was photographed through an absorption tube 6·6 metres long, the methyl iodide having been fractionated twice immediately before use. No bands were found; but the continuous absorption was found to extend practically to λ 3600, which is some distance beyond the absorption 'limits' of λ 3360 and λ 3100, found by Iredale and Mills[2] and by Hukumoto[3] respectively, using columns of gas 1 metre long. Although the conditions in the long absorption tube made accurate intensity measurements impossible, it was found that the absorption limits in equivalent columns of gaseous and liquid methyl iodide (6·6 metres at 220 mm. and 0·6 cm. respectively) occurred at about the same wave-length, indicating that the absorption coefficients of liquid and gas in this region are of the same order of magnitude. Since Iredale and Wallace[4] found that 4 cm. of the liquid absorbed as far as λ 3950, a result that was confirmed in this laboratory, an equivalent column of the gas of the rather impracticable length of 40 metres should absorb at wave-lengths considerably longer than λ 3600, so that the existence of a band system in this region, though improbable, cannot be entirely ruled out.

The experiments also emphasise the fact that the determination of absorption limits by extrapolation from results obtained with short columns of gas may lead to values which are in error by many hundreds of Angstrom units, and that results so obtained have no thermochemical significance.

Points from Foregoing Letters

Prof. G. Beck discusses the forces binding the constituent parts of the nucleus of the atom and inquires into the reasons why two electrons are not emitted simultaneously in radioactive changes; he considers that this would involve the simultaneous occurrence of two neutrinos (neutrino and anti-neutrino).

The half-life periods and the maximum energy of the electrons emitted by a number of artificial radio-elements obtained by neutron bombardment are given by Prof. A. I. Alichanow, A. I. Alichanian and B. S. Dželepow. The authors point out that their findings do not agree with Fermi's theory of beta ray decay and do not fit in Sargent's diagram, which connects the maximum energy of emitted electrons with the disintegration constant.

In order to determine the velocity of slow neutrons, Dr. O. R. Frisch and E. T. Sørensen have investigated the effect of passing the neutrons through the marginal part of a rotating wooden disc, and observing the effect of the emerging neutrons upon boron-lined ionisation chambers at two different angles; the results indicate that a large part of the neutrons have velocities of the order of 200 metres per second, and further experiments with cadmium screens show that the main part of those neutrons which are strongly absorbed in cadmium have such thermal velocities.

Dr. E. Tschopp finds that androstendione surpasses other known male hormones in its action upon the growth of the sex organs of the male rat, though, as is the case with the testicular extract, its effect upon the growth of the capon's comb is inferior to that of androsterone. This and other evidence supports the view that androstendione is a constituent of the male hormone of the testes.

Thin films (mono-molecular) of myosin, a constituent of muscle protein, floating upon water solution, are expanded by potassium lactate at *p*H 7, and the expansion increases at higher *p*H (alkaline solutions). A. A. Moss, Jr., Prof. Eric K. Rideal and E. C. Bate Smith consider that these phenomena may throw some light on the changes which take place in the muscle, the lactate helping in the relaxation of the fibrils during recovery.

Hydrogen molecules are more readily dissociated by the impact of electrons moving parallel to the molecular axis, according to Prof. N. Sasaki and T. Nakao. The authors give a diagram of the apparatus used in measuring the angular distribution of the resulting ions.

The influence of a magnetic field upon the viscosity of an anisotropic liquid (*p*-azoxyanisol at 125° C.) has been re-determined by M. Miesowicz, from the damping effect upon an oscillating plate. He finds that the viscosity is increased 3·5 times by a magnetic field of 2,400 gauss.

Clover plants have been grown by Prof. P. W. Wilson in a closed system under pressures of 0·12–1·8 atmospheres. At pressures greater than atmospheric the development of plants appeared to be normal; between 0·20 and 1·00 atmosphere, stimulation of growth was evident. Below 0·20 atmosphere, development was restricted, apparently because of low pressures of oxygen available. At extremely low pressures occasional freak growths were encountered.

N. S. Bayliss describes the ultra-violet absorption spectrum of methyl iodide, photographed through 6·6 metres of the gas. The continuous spectrum was found to extend to at least λ 3600, and although no accompanying band system was found, the possibility of one cannot be entirely dismissed.

Research Items

Excavation in Brittany

IN 1929 Sir Robert Mond was invited to undertake the exploration of the Tressé *allée couverte* by Baron Robert Surcouf, its owner, and entrusted the work of excavation to Miss V. C. C. Collum. This megalithic monument is situated in the Forêt du Mesnil, Ille-et-Vilaine, and had not previously been explored, although it had been reported in 1880 and then scheduled as an ancient monument. Excavation took place in April 1931, and an account of the results then obtained has now been published ("The Tressé Iron-Age Megalithic Monument (Sir Robert Mond's Excavation)". By V. C. C. Collum. Pp. xii+123, with 35 pls. Oxford University Press. 10*s*. 6*d*. net). The objective of the investigation was to test the generally accepted view that megalithic monuments in Brittany, such as this, have suffered 'violation' and disturbance in an age long subsequent to that of their erection. Careful and detailed records of excavation and stratification, therefore, were made. A peculiar and characteristic feature of the monument is the occurrence of two double pairs of sculptured human breasts, one double pair on a transverse stone blocking the northern end of the *allée*, the other on the western upright of the alcove beneath the transverse stone. In brief, the results of the investigation indicate that this is a native Gaulish tomb erected in the first century A.D., probably in the reign of Domitian. Fragmentary skeletal remains, not cremated, associated with pottery, both wheel and hand-made, steatite beads, iron which may have been part of a fibula adorned with bronze, and 'nondescript' flint and chert implements, together with the representation of female breasts, point to burial offerings to the mother-goddess or female principle, of which the cult was widespread in Egypt and the East, and at the date suggested as that of the megalith, incorporate in Eastern mysticism. The cult, it is suggested, reached Brittany and Great Britain by way of the Mediterranean, North Africa and the Iberian coast.

Iron Age Pottery in Britain

DR. R. E. MORTIMER WHEELER appends to his report on the excavation in 1934 of Maiden Castle, Dorchester (*Antiquaries J.*, **15**, 3), an important, though provisional, amended classification of the Iron Age pottery of Britain. A previous classification, proposed by Mr. Christopher Hawkes, recognises three groups or cultures: *A*—composite, mainly Hallstatt, the type-site being All Cannings Cross; *B*—marsh-village culture of Glastonbury and Meare, pottery with elaborate curvilinear decoration, pre-eminently 'Celtic'; and *C*—Belgic immigrant culture, deficient in artistic expression, but technically well equipped, having the potter's wheel. Geographically, *A* is found over most of middle and southern England, and may be recognised so early as the sixth century B.C., remaining dominant in Oxfordshire, Kent and other south-eastern counties down to the first century B.C. In the west, it is replaced by *B* in the second century B.C., while the Belgic culture enters the south-east in the first half of the first century B.C. *B* occurs primarily in the south-west, but extends on one hand, to Northamptonshire and Lincolnshire and, on the other, eastward into Sussex. There is no good evidence for *C* in Wessex before the beginning of the first century A.D. Provisionally, it is proposed to subdivide *A* into three parts: *A*1, 600–400 B.C., marked by finger-tipped ornament especially on high-shouldered *situla* types, and red-coated ('hæmatite') bowls, at first with rilled, and later with cordon decoration; *A*2, 400–200 B.C., absence of above types and presence of poor derivatives of *situla* type, coarse, rough but light fabric, no decoration (well represented at Maiden Castle); *AB*, 200 B.C. to early first century, smaller and simpler types of *A*2, with pottery of *B* types. Class *B*, hitherto regarded as synonymous with Glastonbury, is now seen to be a complex of two or three elements of diverse origin. Decoration is not an adequate criterion. In its place is suggested the bead rim and the counter-sunk handle, neither of which occurs in *A*. The Belgic pottery does not reach Maiden Castle until the eve of the Roman conquest. Reproduction of modified *B* types with the aid of the potter's wheel suggest a composite culture *BC*.

Inbreeding of Swine

VARIOUS experiments on inbreeding of pigs have led to the conclusion that it is injurious to the race. In an experiment which has been continued for eight generations by Mr. R. E. Hodgson (*J. Hered.*, **26**, No. 5) at the Experiment Station of the University of Minnesota, he reaches somewhat different conclusions. Brother-sister matings of registered Poland-China swine were made for eight generations without any marked loss of vigour. The strains chosen appear to have been exceptionally free from deleterious recessive characters. The experiments began with six sows, the strain from one being used as an outbred control. Three of the inbred lines were lost in the first generation and a fourth in the second generation, due to reluctance to mate. In 1926 two new lines were started, one of which is now in the sixth and the other in the eighth inbred generation. The difficulty in securing matings has been less since the fifth generation, and it appears that the strains can now be propagated indefinitely by brother-sister mating. A few anomalies have appeared, and some undesirable characters were segregated, including odd psychological and physiological sexual reactions. Evidence was obtained that differences in disposition, such as super-docility and wildness, are inherited. A substrain with yellow and another with white blotches was segregated from one line. Comparison with the non-inbred strain indicates that no vigour has been lost, but that segregation of vigour has taken place in some cases.

Seasonal Variation in Oogenesis of a Hermit-Crab

M. K. SUBRAMANIAM (*J. Roy. Micr. Soc.*, **55**, Pt. 1; 1935) has studied the oogenesis of a hermit crab, *Clibanarius olivaceus*, found in brackish water at the mouth of the Adyar River, near Madras. In January and February, after the heavy rains of the retreating monsoon, the sea-water mixes freely with the river-water, and the bar at the mouth of the river is

open. From the middle of March the level of the water in the river begins to fall, with consequent widening of the bar, and in early April the sea invades the river only at high tide, and even this ceases by mid-April. The crab was found to breed throughout the year but especially in the period from September to March. The ovaries were removed and carefully preserved, and the oocytes examined. In January and February the oocytes showed a voluminous formation of fatty yolk and the occurrence of albuminous yolk. From April to June there was less fatty yolk in the oocytes but more albuminous yolk. The author states that during the period from November to the middle of April, the salinity of the estuarine water is high, but later, as the bar closes, the salinity is suddenly lowered and there is a rise in the *p*H. The author supposes that the alterations in the condition of life of the crab may have led to a variation in the metabolism which may have affected the constitution of the oocytes.

Diseases of the Iris

A SHORT article by Mr. G. N. Bunyard, in the *Gardeners' Chronicle* for June 29, describes four diseases of Iris plants. Leaf spot, caused by the fungus *Heterosporium gracile*, and Leaf rust, *Puccinia iridis*, are two diseases of the foliage, and may assume serious proportions. Ammoniacal copper carbonate and potassium sulphide do not control either malady, but the simple routine of dividing the rootstock every second year gives healthy produce. Rhizomes and roots are subject to 'scorch' and 'rhizome rot', but no organism has yet been identified as the cause of either disease. Both may be controlled by lifting the rhizomes, cutting away the rotten parts, and then bathing the rest in a bright pink solution of potassium permanganate for twenty minutes. Planting in a 'hospital' bed containing peat and sharp sand further assists the progress of recovery.

Poisoning of Plants by Fluorine

ESCAPE of hydrofluoric acid during chemical operations in which ores rich in fluorides are treated with mineral acid is not easy to prevent, especially when steam is simultaneously liberated, and it may result in damage to the vegetation of the surrounding neighbourhood. An ingenious biochemical method of detecting poisoning of plants by the acid has been devised by Prof. Angelo Contardi in conjunction with Carlo Ravazzoni (*Rend. R. Ist. Lombardo Sci. e Lett.*, **68**, parts 6–9). The method is based on the observations (1) that hydrofluoric acid, which attacks the leaves of plants, remains for a long time in the form of soluble compounds capable of inhibiting the enzymic action of the acid phosphatase of rice husk, and (2) that the insoluble fluorides normally present in leaves exert only a very feeble action on this enzyme. The aqueous extract of the leaves under examination is evaporated to dryness, ignited and fused with sodium carbonate, the cold mass being then dissolved in water and the solution filtered. A second solution is prepared similarly from normal, unpoisoned leaves of the same kind of plant, and the effects of the two liquids on the enzymic action are compared.

Respiration of Barley Leaves

THE relation between carbon dioxide production and the concentration of the various carbohydrates during starvation of isolated barley leaves has been investigated by E. W. Yemm (*Proc. Roy. Soc.*, B, **117**, 483–525; 1935) using a combination of iodometric and modified Hagedorn-Jensen methods for the estimation of glucose, fructose, maltose and sucrose. Non-sugar impurities were determined separately after removing all the sugars by yeast fermentation. Carbon dioxide production shows a rise during the 12 hours immediately after isolation, and the subsequent rapid fall is interrupted after about 40 hours by a stage coinciding with the yellowing of the leaves. Finally, the respiration falls rapidly, concurrently with browning and death of the cells. No simple quantitative relation exists between the concentration of any individual carbohydrate and the rate of carbon dioxide production; and, moreover, it is only in the initial stages that all the carbon dioxide arises directly from the available carbohydrate. During the remainder of the time, as much as 75 per cent of the carbon dioxide production arises from some undetermined source other than carbohydrate, and this production is less when the initial sugar content is high, that is, progressive carbohydrate exhaustion increases the production of carbon dioxide from undetermined sources. Determinations of the respiratory quotient suggest that this carbon dioxide arises from protein breakdown. (A similar conclusion was reached by Dastur and Desai with rice seedlings, *Ann. Bot.*, **49**, 53; 1935.) It is suggested that rapid sucrose hydrolysis is followed by glycolysis of fructose and accumulation of glucose, which disappears more slowly. Essentially similar results were obtained with bean leaves.

Grass Land Problems in South Africa

ANY traveller in South Africa must be impressed with the wide expanse of country, often comparatively high tableland, which is covered with a grassland dotted throughout with scattered trees, a typical savannah country. Botanically, such country is of the greatest interest as it always raises the question whether such a precarious balance between two types of vegetation will be maintained or whether the trees will close over and subdue the grass or the grass gradually choke out the trees. Economically also the problem is of the utmost importance, this balance of grass and trees being influenced by the head of game or by the amount of stock carried, and by the practice, or lack of regular practice, in seasonal burning of the veldt grasses. It is very fitting therefore that the new *Journal of South African Botany*, issued under the authority of the trustees of the National Botanic Gardens of South Africa and edited by Prof. R. H. Compton, director of the Kirstenbosch Gardens, should include in part 2 of its first volume, a very interesting general discussion of South African grassland problems by Prof. J. Phillips, of the University of the Witwatersrand. Under his direction, problems of grassland ecology are being attacked at the Botanical Research Station of the University at Frankenwald, in the high veld, and a preliminary study of the root systems of some of the characteristic high veld grasses, by Messrs. S. M. Murray and P. Glover, carried out at this station, is reported upon in the same journal. This study shows that very fundamental differences may be found in the root systems of pioneering species and other species; whilst Prof. Phillips's paper shows the very wide nature and great economic importance of the problem raised by the study of these grasslands.

Evaporation in India

AN investigation into evaporation in India has been made in the Agricultural Meteorology Branch of the India Meteorological Department by P. K. Raman and V. Satakopan. The work is described in Scientific Notes, 6, No. 61 (Delhi: Manager of Publications). As the authors remark, "our knowledge of evaporation from the soil under natural conditions is practically nil in India", and they have had to content themselves with a study of the evaporating power of the atmosphere with respect to a free water surface, and to calculate this from various meteorological factors such as mean wind velocity, mean relative humidity and mean water vapour pressure, by an empirical formula. The formula chosen was derived from a formula of Carl Rohwer based on laboratory studies made with the view of testing separately the effect of the different factors. In Rohwer's formula, a factor $e_s - e_d$ appears, where e_s is the mean vapour pressure of saturated air at the temperature of the water surface and e_d is the mean vapour pressure of saturated air at the temperature of the dew point. In the absence of data for the temperature of free water surfaces in India, the rather bold assumption has been made that calculation of mean values can be made as though the temperature of the water is the same as that of the air, which is possibly true when one is dealing with averages. In that case, $e_s - e_d$ becomes $(100/h - 1)\,e$, where h is the relative humidity of the air and e is its vapour pressure. Calculated means of evaporation for a well distributed network of stations for each month are tabulated, together with the mean monthly rainfall. The evaporation is shown cartographically on maps of India, also the annual evaporation and the annual figures for rainfall minus evaporation. As might be expected, the area of greatest evaporation is in the west of India, with its centre in about latitude 20° N.

Activation and Evaporation of Adsorbed Atoms

J. E. LENNARD-JONES and C. Strachan (*Proc. Roy. Soc.*, A, June 1) have made a wave-mechanical calculation of the probability of activation of adsorbed atoms, and Strachan in a second paper extends the calculation to obtain probabilities of evaporation of atoms from surfaces. The atoms adsorbed on a crystal lattice may remain in one place, vibrating about a mean position, they may migrate from place to place or they may be ejected from the surface by the heat motion of the lattice atoms. The vibrations of the atoms about a mean position provide the activated energy states which are considered in this paper. The atoms are assumed to be adsorbed as a simple cubic crystal and the forces holding them are supposed to be of the Morse type in which the potential is given by two exponential terms corresponding to a short-range repulsive field and a long-range attractive field. Formulæ are found for the probability of excitation of different excited vibrational states and for the average life of an atom in an excited state. The life of an excited state seems to be of the order of 10^{-12} sec. in a particular case—this time is a few periods of the vibratory atom. The migration of atoms over the surface takes place when the atoms are in an activated state. The evaporation problem involves an extension to the case of transitions to a state in the region of continuous energy distribution. The theory is worked out and applied to the cases of H_2, HD and D_2. The surface forces are nearly the same for these molecules; the different masses lead to different wave functions and the probabilities of evaporation from a surface at low temperature in these molecular species are roughly in the ratio 1, 0·2, 0·05.

A New Power Output Valve

IN the best types of modern broadcasting receivers, the output valve is usually of the triode or three-electrode type, since this enables the most complete freedom from distortion of the acoustic output to be obtained. This valve is, however, relatively insensitive, so that an additional stage of audio-frequency amplification is required, rendering its use uneconomic in the majority of commercial receivers. Such receivers therefore usually employ a pentode output valve, which will give the same output power for about one third of the input voltage required by the corresponding triode. The pentode output valve is very liable to produce distortion due to curvature of its characteristics over a considerable portion of its working range. This defect is claimed to have been removed in a new type of power output valve described by J. H. Owen Harries in the *Wireless World* of August 2. The new valve is of the four electrode type, the cathode and two grids being of normal construction and dimensions; the novelty lies in the fact that the anode is a cylinder of unusually large diameter. It has been found that if the anode of a multi-grid valve is spaced from the outer grid at a certain critical distance, the undesired secondary emission is eliminated, and the consequent necessity for a suppressor grid, as in the pentode, is avoided. Characteristics of the new valves in comparisons with those of typical pentodes illustrate the improvement which has been obtained in linearity and resultant freedom from distortion. The impedances of the new valves are lower than those of the equivalent pentodes, while the mutual conductances are appreciably higher, thus giving about the same overall sensitivity. It is stated that the High Vacuum Valve Co. is now manufacturing these new valves in a two-watt output type, which is considered to be adequate for the average domestic user.

Structure of a Stellar Atmosphere

W. H. CHRISTIE and O. C. Wilson (*Astrophys. J.*, 81, 426) have described an interesting method of examining the structure of a stellar atmosphere in the case of the eclipsing binary ζ Aurigae. This system consists of a giant K-type component with a B-type companion, and the authors have devised a method whereby the effects of the light of the former may be eliminated from the composite spectrum, thus permitting a study of the light from the B star shining through the atmosphere of the K star. A series of spectra taken near the period of eclipse will thus give the relative heights to which various elements extend in the atmosphere of the K star, and also the relative number of atoms existing at different levels above the photosphere. Changes in the total absorption have been measured for nearly 100 lines in spectrograms taken at Mount Wilson during the 1934 eclipse, and the results grouped into the following six classes: neutral metals, Mg, Ti II (two groups), H, and Ca II. Accurate photometric observations are still badly needed to improve the values of essential factors such as the relative diameters of the two components and the inclination of the orbit. It is hoped that these will be forthcoming during the next eclipses in 1937 and 1939.

Tectonic Framework of China

PROF. J. S. LEE delivered a lecture before the Geological Society on June 5 on a subject of which he is the leading authority: "The Structural Pattern of China and its Dynamic Interpretation". Since the time of Suess, it has been generally accepted that the structural framework of eastern Asia consists of a series of arcs with the 'Amphitheatre of Irkusk' as their common centre. Modern researches, however, have shown that each of these arcs embraces features of different tectonic origin. Three main groups of structural elements are now recognised: (*a*) the Cathaysian geosynclines and their complementary geanticlines; (*b*) the east-west zones; and (*c*) the shear-forms. These seem to be fundamentally independent of each other, although they sometimes fall in line and sometimes interfere.

The Palæocathaysian geosyncline existed as an epicontinental trough, more or less parallel with the eastern border of the continent, so far back as late Pre-Cambrian time. A remnant of its borderland still remains in the coastal belt of south-eastern China. Prof. Lee traces its history to Permo-Carboniferous times, when it formed the eastern extension of the Tethys, and on to the Triassic when it formed the Mesocathaysian geosyncline. It was completely filled in during the Lower Jurassic, and since then China has remained continental. Modern features arose from Jurassic-Cretaceous movements and some of them followed the old-established lines, with the result that geosynclines and geanticlines of the Cathaysian type can still be recognised. One of the present-day troughs is occupied by the Sea of Japan and the Yellow Sea; another, farther inland, stretches from the plain of Manchuria to the Central Yangtze Basin and is named the Neocathaysian geosyncline.

The east-west zones, tabulated below, exhibit a rhythmic orogeny that is one of the most striking tectonic phenomena of eastern Asia. It will be noted that the interval between the ranges is 8° of latitude in every case.

The third group of features includes various shear-forms, of which three types predominate. One of these forms consists of a series of nearly parallel folds trending north-east or north-west and is known as the ξ type. These are commonly traversed by faults roughly perpendicular to the axes. Another consists of a frontal arc with a radial backbone, somewhat after the fashion of a bow and arrow, and is called the ε type. The third is a bundle of folds curving round an old massif or mountain mass and is designated the η type.

Orogenic Epochs	Ranges and their latitudes			
	Tannu-Kentai 49°–50°N.	Inshan 41°–42°N.	Tsingling 33°–34°N.	Nanling 25°–26°N.
Tertiary	—	×	?	?
Jurassic-Cretaceous	×	×	×	×
Hercynian	?	?	×	×
Caledonian	×	—	?	×
Pre-Sinian	×	×	×	×

Consideration of the mechanics, supported by experimental reproductions, leads Prof. Lee to the belief that the shear-forms imply horizontal shearing movements of the upper layer of the continental mass, directed on one hand against the Tibetan massif or the shattered ends of the east-and-west ranges, and on the other against the border of the continent. The other features also suggest southerly movement of the continental mass, and it is suggested that the driving force might have been supplied by an increased speed of rotation of the earth due, for example, to concentration of mass in the interior or to bodily contraction of the earth as a whole. An attempt is made to test the hypothesis by the distribution in time and place of the marine transgressions of the past, some twenty-one of which (major cycles) are recognisable since the beginning of the Cambrian. For a more extensive summary of the lecture, reference should be made to *Abs. Proc. Geol. Soc. London*, No. 1298, June 17, 1935.

Return of Mineral Elements to the Soil by Plants

IT is not generally known that plants can return to the soil at some stage of their growth, either after the first burst of vegetative activity or after maturation of the fruits, certain of the more important nutrient elements which they have absorbed.

Until recently the evidence was meagre, but a series of papers published in Bucharest by Prof. Deleanu and his colleagues[1–3] recording the result of investigations into the function of mineral elements in the life of the plant, has added considerably to our knowledge of this phenomenon.

In 1908 Prof. Deleanu himself[4] found that there was a reversal of the process of absorption of soil constituents, called by him 'negative migration', which occurred in oat plants after they had reached maximum growth, the loss being 64 per cent of the ash elements and 47 per cent of nitrogen. In 1919 J. S. Burd[5] recorded that with barley grown on two different soils, the initial progressively increasing rate of absorption of the soil constituents during the early stages of vegetative development was followed by a period of actual loss, coincident with the development of the heads, and succeeded by renewed absorption at a later period. The absorption and loss were most marked in the elements potassium and nitrogen. In maize the rate of absorption decreased considerably prior to head formation, though no actual loss of soil constituents was found[6]. Plants such as the potato, on the other hand, show no such striking change in the rate of absorption.

In the recent Bucharest investigations, V. G. Bossie[2], working with wheat, shows that the cycle of absorption and migration is somewhat similar to that of barley, differing only in details. The life period of some seventy days in wheat can be divided into three phases: (1) vegetative, which reaches its maximum by the twenty-sixth day; (2) fruiting, which commences about the thirty-first day and culminates about the sixty-fifth day, and (3) post-maturity. Absorption of all mineral elements in the aerial portions as a whole was rapid and very considerable during phase (1); thereafter the rate of absorption of phosphorus, nitrogen and magnesium was markedly decreased, but none of these was lost, whereas in the case of potassium and calcium actual loss occurred after the first twenty-six days; silica, which amounts to nearly half the total ash, continued to be absorbed more or less regularly until maturity, when some loss of all elements occurred. The amount of the loss was most marked in the case of potassium and calcium, as negative migration of these had started early, but the loss in all other cases was less than 20 per cent. What is happening is that during the stage (2) the developing ear is drawing its supplies of nutrients from the leafy stems, silica only being absorbed directly from the soil; the supply of nitrogen, phosphorus and magnesium is inadequate in the leaves and so a further slight absorption of these elements from the soil takes place; potassium and calcium, however, are in excess of the amount required by the ear, and so can be returned to the soil.

The phenomenon of negative migration occurs in other groups of plants. In tobacco, for example, not only does loss of soil constituents occur when the main stem has reached maturity, but it may also be succeeded by re-absorption and further negative migration corresponding with the development of axillary shoots[3].

It seems obvious, therefore, that the reason for the changes in the rate of absorption by the plant must be sought in the metabolic state of the tissues, and that when actual loss occurs it is probably due to the interaction of the factors causing the metabolic changes and the factors of the soil environment affecting absorption. In this respect it is well to mention that Burd[5] found that the losses occurred in oats when the constituents of the water extracts of the soil were at or approaching their minima and when the same constituents were moving from the leaves to the ear.

It has been suggested that the elements migrating from the aerial organs are accumulated by the roots. In the paper by Bossie, however, details of the analyses of roots have been included, and bearing in mind the difficulties attending collection of these organs from the soil, the results show that this cannot be the case; for example, from the twenty-sixth day to the thirty-fifth day, the aerial organs of a hundred wheat plants lost 0·187 gm. of potassium, whereas the roots only accumulated 0·001 gm. in the same time; the other 0·186 gm. must therefore have been returned to the soil.

Third Imperial Mycological Conference

IN spite of financial stringency, which has cramped the activities of many scientific institutions of recent years, the Imperial Mycological Institute organised a very successful Conference at the Imperial College of Science and Technology in September 1934. Invitations were conveyed to overseas Governments of the British Empire, to certain Government Departments of the United Kingdom, and to the staffs of agricultural and horticultural research stations, university departments, to individual mycologists, and to the representatives of certain firms interested in the manufacture of fungicides. A report of the activities of this Conference has recently appeared (Imp. Mycol. Inst., Kew, Surrey, pp. 32, 2*s*. net).

Sir Charles Howell Thomas opened the proceedings of the Conference on September 17. In the course of his speech of welcome, he referred to the change in administrative control of the Institute, and praised the work of Lord Buxton in fostering the efficient work of the Institutes of Mycology and Entomology before they were taken over by the Executive Council of the Imperial Agricultural Bureaux. The future finance of the Institute of Mycology gives cause for concern, and was the subject of deliberation by a special sub-committee. It was recommended that representations be made to the various Governments supporting the Institute for restored or increased financial aid.

The Director (Dr. E. J. Butler), in reviewing the work of the Institute, showed that enormous financial losses are sustained as a result of fungal attack, and stressed the importance of disease surveys in demonstrating such loss. He also discussed the publication of the Institute's periodical *Review of Applied Mycology*.

The deliberations of the Conference naturally covered a wide field. Administrative measures against plant diseases, methods of standardisation of insecticides and fungicides, virus diseases, control methods for small cultivators, foot-rots of cereals, breeding and selection for immunity against disease, and several papers on diseases of particular crops, formed the main topics.

One important activity of the Conference lay in the drafting of a health certificate to be given to consignments of plants made within the Empire. This is not designed to replace any legislation or quarantine regulations, and carries nothing but a hall-mark of freedom from disease. If this practice is adopted extensively, it should mark a very considerable advance in the control of fungus diseases.

Radiation from a Transmitting Aerial

THE transmitting aerial of a broadcasting station designed for local or national service should confine as much as possible of its radiated energy to the horizontal direction, emitting as little as possible in directions making an angle of less than 60° with the vertical. The station will then have a large service area in which little fading is experienced. The demand for information on the design of such an aerial has given rise in recent years to some theoretical and experimental investigations on the general properties of antennæ used in radio transmitting stations.

A new and useful contribution to the state of knowledge on this subject has recently been given by Prof. P. O. Pedersen in a booklet published (in English) in Copenhagen ("Radiation from a Vertical Antenna over Flat Perfectly Conducting Earth." Pp. 49+35 figures. G. E. C. Gad: Vimmelskaftet 32, Copenhagen. Kr. 6.00). This work comprises a theoretical investigation of the radiation characteristics of a vertical antenna over flat perfectly conducting earth, having for its objective a determination of the most suitable dimensions of the antenna at the new Copenhagen broadcasting station. The theoretical results have been checked by measurements of the distribution of the current in the antenna and of the field intensity at various distances from the station. To facilitate the theoretical analysis, the current distribution in the transmitting antenna is in the first case assumed to be sinusoidal, although it was known that this is not valid in the practical case. The complete general formulæ for the radiated field for an antenna are obtained, and a most useful series of tables and graphs are provided, from which the radiation resistance and the distribution of the radiated field in the vertical plane may be calculated for antennæ of various dimensions.

The author then applies the results to the practical case of the vertical antenna at the Copenhagen station. Measurements of the current and voltage distributions in this antenna have been made to ascertain to what extent they differ from the sinusoidal case. The chief point of difference is that the node of current at the base of the antenna, which is just over half a wavelength high, is replaced by a current minimum only. The formulæ are therefore recalculated to take account of this new distribution, and it is shown that the alteration produced in the radiation distribution diagram for the Copenhagen antenna is almost negligible.

The practical and very satisfactory result of the work described in this paper is, therefore, that for the type of half wave transmitting aerial which is now employed at many broadcasting stations, the radiation characteristics may be calculated with good approximation by the comparatively simple analysis based upon a sinusoidal distribution of current in the antenna.

Work of the Bureau of Standards, Washington

ALTHOUGH owing to the necessity for economy the work of the U.S. Bureau of Standards had to be appreciably curtailed last year, yet the record of the work done as given in the annual report of the Secretary of Commerce (pp. 51–76) is impressive and interesting.

Valuable results were obtained in an experimental research on the transmission utility of the various frequencies used in broadcasting. The effects of ground waves and sky waves were determined. The sky waves were found to play a far more important role in distant daytime reception than was formerly supposed. The results obtained by measurements throughout the year on the height and ionisation of the conducting layers in the upper atmosphere which are responsible for long-distance radio transmission have greatly increased our knowledge of the subject. The relative effects produced by ultra-violet light, electrons and heavy ions have been determined.

Tests show that a new method of assembling watches having monometallic balance wheels and elinvar hairsprings has increased the uniformity of their time-keeping and has practically eliminated the deleterious effects that can be produced by magnetism. In association with the American Dental Association, the Bureau has developed and standardised methods for tarnish tests for dental alloys of low precious metal content. In connexion with criminal work, assistance was given in cases involving extortion, kidnapping, forgeries, threatening letters, etc.

The temperature of 'freezing' rhodium *in vacuo* has been found to be 1,966° C. with a possible inaccuracy of ± 3° C. The candle-power of tungsten filament lamp standards can now be found from the basic carbon filament standards. The vapour pressures of solid and liquid heavy hydrogen (deuterium) have been measured and from these data its freezing and boiling points and latent heats have been deduced. Interference measurements in the first spectra of several gases have been repeated and extended. Most of the spectral lines have been found reproducible to one part in fifty million and consequently are recommended as standards for spectroscopic and meteorological measurements.

Many useful hints are given amongst the results obtained. For example, tests made under carefully controlled conditions, with lighted cigarettes on grass and forest floor materials, show that the fire risk is greatly decreased when a cigarette paper tip ¾–1 in. long is applied in the course of manufacture over the end that is discarded. The possibility of utilising this result in practice is worth considering. The carpet wear-testing machine developed at the Bureau has been put to good use during the year. It has been found that the durability of a carpet is materially increased by increasing the density or the height of the pile and by the use of underlays.

Colour Inheritance in Silkworms

IMPORTANT results and conclusions regarding the inheritance of cocoon colour in silkworms have recently been published*. In these insects the colour of the silk secreted generally corresponds with that of the hæmolymph. Breeds with white cocoons have colourless blood, while those with yellow cocoons have yellow blood. In different strains the yellow varies from golden to straw-colour or reddish yellow, and some silkworms with yellow blood may weave a white cocoon, but it is not possible for a silkworm having white blood to produce a yellow cocoon.

It is concluded that migration of pigment takes place from the blood to the silk secretion. In some strains there is a change of colour in the different layers of the cocoon. For example, in the Chinese the outer layer is yellow-gold, becoming gradually paler to pure white in the innermost layer. The cocoon of the Italian strain, however, is colourless outside, becoming deeper coloured towards the interior. The colour is derived from the carotinoid pigments of the mulberry leaf, but its tint and distribution appear to depend on the conditions in which the pigment passes from the blood to the silk.

Two races with white (W) cocoons may, when crossed, produce a strain having yellow (Y) cocoons if one is white because the blood is unpigmented and the other because of incapacity of the silk gland to extract pigment from the blood. The possibility of migration of blood pigment to the silk is inherited as a dominant Mendelian character, but races differ in the time at which the silk glands show this capacity for taking up pigment. Thus in the Italian strain 'Fossombrone' the cocoon is nearly white in its outer layers, becoming golden yellow within, while in the Chinese yellow the outer layers of the cocoon are yellow. In crosses between them, this difference in 'precocity' of the action of the silk gland gives an intermediate result in the hybrid. Such results account for various discrepancies and the 'maternal inheritance' obtained by earlier investigators.

The colourless blood and white cocoons of the Japanese 'Awojiku' and other recessive whites is believed to be due to absence of capacity for absorbing the carotinoid pigments from the food through the intestinal wall; while in such dominant white strains as 'Baghdad' the colourless blood may be due to the presence of oxidising enzymes. In a green strain the pigment is a flavone derived from the leaf, which is present also in certain other strains. Thus not only are intestinal permeability and glandular permeability independent, but permeability to the flavones and the carotinoids are separate characters. White 'Awojiku' × 'Green' gives an F_1 with white blood and a 15 : 1 ratio in F_2. The explanation of this dihybrid result is not yet clear.

It is found that the pigments can be quantitatively extracted from the cocoons of various types. By these methods it is possible not only to reach a physiological definition of the hereditary factors in terms of cell permeability, but also to investigate the chemico-physiological individuality of the substances the metabolism of which is controlled by these genetic factors.

Educational Topics and Events

CAMBRIDGE.—The Frank Smart studentship in botany will be vacant on October 1, 1935. Any graduate of the University is eligible for the studentship provided that not more than fourteen complete terms have elapsed after his first term of residence. The value of the studentship is £200 per annum. A candidate must send his name, with a statement of the course of research he proposes to undertake, to Prof. A. C. Seward at the Botany School on or before October 2.

FROM the Kaiser-Wilhelm-Gesellschaft zur Förderung der Wissenschaften we have received two polyglot pamphlets describing the scope of the Society's work, which embraces the maintenance of thirty-four research institutes in Berlin, Heidelberg, Dortmund, Munich, Göttingen, Düsseldorf, Breslau, Dresden, the Ruhr and other places in Germany, Austria, Italy, Switzerland and Brazil. An appeal is made for the moral and material support of Germans the world over (in the English version, erroneously, "the widest circles in Germany"). One of the pamphlets relates to "Harnack House" in Berlin, a hostel for foreign visitors engaged in research in subjects germane to those studied in the Society's institutes. Here they have opportunities of intercourse with German savants, for the hostel serves also as a club for members of the Society and the staffs of the Institutes, about 150 of whom take their meals there every day. The House has a library, reading-room with numerous German and foreign periodicals, gymnasium, tennis-courts, bathrooms, lounge, terraces, etc. It is used by various learned societies for lectures and social functions, and is described as having become the centre of intellectual life in Berlin.

UNIVERSITY student housing conditions, past and present, form the subject of two interesting articles by Dr. W. H. Cowley, of Ohio State University, in *School and Society* of December 1 and 8. Nearly all the founders of the American colonial colleges were Oxford and Cambridge graduates or English-educated Americans; but the English college system of bringing together dons and students both for formal individual conferences and for informal social and intellectual intercourse failed to reproduce itself in the United States. College residential conditions were affected not only by the undeveloped state of the country, but also particularly by the bogey of student discipline, responsibility for which rested on the faculty member living in the dormitory, and this led to acute faculty-student antipathies. In the course of the nineteenth century, German university ideals became dominant in America and, as these recognised no obligation on the part of the university to concern itself with the life of the student outside the classroom, dormitories came to suffer from neglect where not dispensed with. Towards the end of the century a reaction began, and though considerably hampered by the recent general economic depression, is still active and promises to become even more important. The Oxford and Cambridge college system has now been adopted more or less at Harvard and Yale, the German point of view still prevails at California and Nebraska, and an American compromise, giving students body shelter and varying degrees of social education, is general.

Science News a Century Ago

Alexander von Humboldt in Paris

IN its column of "Miscellanea", the *Athenaeum* of September 12, 1835, said: "The celebrated Alexander von Humboldt is once more in Paris, and at the meeting of the French Academy of Sciences, on the 17th of August, called the attention of the members to the prints of footsteps, belonging to a quadruped, in the variegated sandstone, or *bunte sandstein* of Hildburghausen. It is an animal of the Plantigrada division, which traversed the rock while soft, and in various directions. A stone containing these impressions, from ten to twelve feet long, and three to four wide, has been sent to the collection of mineralogy at Berlin, of which the Baron submitted a beautiful drawing. There are four or five species of smaller impressions, which cross those of the larger quadruped at right angles, and are remarkable for the unequal dimensions of the fore and hind feet, and all have five toes. The rock is covered with them as with a network, and here and there sinuous serpular concretions, perhaps of plants on which the animal walked, perhaps some accidental effect of drying. The great importance of this discovery lies in the place occupied by this sandstone in the chronological series of rocks."

Earthquake in Lancashire

ON August 20, 1835, according to the *Annual Register*, "A shock of an earthquake was felt in different parts of Lancashire. . . . It was felt at Downham, Wiswell, Pendleton, Milton, Waddington and all the surrounding villages. At about twenty minutes to four o'clock the inhabitants were disturbed by a violent tremulous motion, and the sensation of heaving or rising and falling of the bed in which they lay, which was followed by a distinct noise resembling distant artillery. It was felt in Liverpool and was violent at Lancaster, where it threw down a chimney in Bridge-street, but without doing serious mischief. . . . The shock was felt very forcibly in Preston at about twenty-seven minutes before four o'clock. The noise produced by the internal thunder was likened to the sound of some heavy piece of artillery being dragged very rapidly over a pavement; and the whole duration of the shock to the latest vibratory motion produced by it was not less than thirty seconds."

Death of Leopoldo Nobili

ON August 23, 1835, the Italian physicist Leopoldo Nobili died. Born in 1784, Nobili was in his youth an artillery officer, but he afterwards became professor of physics in the archducal museum at Florence, the old habitat of the Accademia del Cimento. His principal researches were made in magnetism, electricity and light, on which subjects he left a large number of theoretical works. In some of his latter work he was associated with his distinguished countryman Melloni. Nobile made two valuable contributions to science, the first being his suggestion in 1830 of the astatic combination of the needles by which the sensibility of the galvanometer (Schweigger's invention) is greatly increased, and the second his invention in 1834 of the thermomultiplier or thermo-electric pile, which in the hands of Melloni and J. D. Forbes led to the discovery of many important facts. At a time when animal electricity was attracting much attention, Nobile demonstrated the passage of a current of electricity from the feet to the spine of a frog, and he was the discoverer of the beautiful coloured transparent films of metal deposited by electro-chemical processes.

Unveiling of Statue of Cuvier

ON August 23, 1835, a statue of Cuvier, who died on May 13, 1832, was unveiled at his birthplace, Montbéliard in the department of Doubs. The statue was by the sculptor Pierre Jean David (1789–1856), and was executed at Belleville, where it had been on view to the public. Deputations from many societies were present and orations were delivered in honour of the occasion. The house in which Cuvier was born was tastefully decorated and on it was placed the inscription—"Ici naquit G. Cuvier, le 23 Août 1769".

Death of John Macculloch, F.R.S.

ON August 21, 1835, Dr. John Macculloch, geologist to the Trigonometrical Survey, died at Penzance through injuries sustained in a carriage accident. Born in Guernsey on October 6, 1773, he attended schools in Penzance and Plymouth; he entered the University of Edinburgh and in 1793 graduated M.D. At first an assistant surgeon in the artillery, he became chemist to the Board of Ordnance, practiced in Blackheath, and in 1814 was appointed lecturer in chemistry and mineralogy to the Royal Military Academy, Woolwich, and geologist to the Trigonometrical Survey. He made several excursions in Scotland, published a "Description of the Western Islands" and prepared a geological map of the country. He was elected a fellow of the Geological Society in 1808, and served as president in 1816–17. In 1820 he was admitted a fellow of the Royal Society: "As an original observer," said Lyell, "he yields to no other observer of our own time and is perhaps unrivalled in the wide range of subjects in which he has displayed great talent and profound knowledge." His portrait by Faulkner is preserved by the Royal Society.

GENEVA

Society of Physics and Natural History, June 6. C. E. G. STUECKELBERG: The signification of multiple times in the theory of quanta. L. SCHAMES: The field between an α-particle and an atomic nucleus. Transforming a formula previously deduced for the potential between an α-particle and an atomic nucleus, it can be shown that this potential depends only on the ratio of the mass m to the atomic number, Z. For the same ratio, the potential curve divided by Z is the same. L. SCHAMES: The principal difference between the material mass and the magnetic mass. The magnetic masses can be cancelled by transforming into radii whilst for material masses no plausible reason is known at present for such cancellation. Consequently it is only 0·001–0·0005 of the entire mass which can be emitted in stars. This radiation finished, the star is composed only of neutral and material mass of very great density. J. WEIGLE: Molecular fields in the liquid state. The presence of a quasi-crystalline orientation of the molecules of a liquid gives rise to a field of force which opposes the rotation of the molecules. The variation of the mean electric moment of nitrobenzene in different non-polar solvents is attributed to the presence of this field, the magnitude of which can be calculated starting from experimental data. Up to concentrations of 50 per cent, this field depends on the solvent and on the nitrobenzene. But above 50 per cent the molecules of nitrobenzene alone determine it. H. SAINI: The thermal expansion of calcite. Measurements of the expansion of calcite, made between 25° C. and 100° C. by means of X-rays on a specimen coming from Mt. Big Timber, have given the same results, within the limits of the experimental errors, as those obtained macroscopically by J. B. Austin. Earlier measurements made by the X-rays on another specimen had given smaller coefficients. FERNAND CHODAT and M. RAAD: The variation of the buffer coefficient of culture fluids in the course of transmissible lysis. A. MERCIER: The expression of the second principle of relativist thermodynamics by means of Clifford numbers. W. H. SCHOPFER: Researches on the role of vitamin B on the nitrogenous metabolism of the Phycomyces. Quantitative researches show that the action of pure crystallised vitamin B is closely related to that of asparagin. Asparagin and vitamin B may be limiting factors with respect to each other. In the case of Phycomyces, it appears that it is especially the nitrogen metabolism which is controlled by vitamin B.

SYDNEY

Royal Society of New South Wales, June 5. EDGAR H. BOOTH: A regional magnetic survey. District: Mittagong–Bowral, New South Wales. This paper presents the corrected observations, over a region of twelve square miles, of a detailed vertical variometer survey. The area is particularly rich in igneous intrusions and flows, and provides a wide variety of both positive and negative anomalies for such detailed study, each isolated phenomenon dropping into place in the regional survey. The work was originally commenced to check whether the micro-syenite intrusion, "The Gib", which rises some 800 ft. between Bowral and Mittagong, was a plug; and developed into a regional survey, when it was found to be an asymmetrical laccolith. Particular attention is given to the examination and discussion of negative anomalies. The instrument employed was a Schmidt type vertical variometer. More than a thousand stations were employed, readings being correct to within 4γ over areas of slight variation (syenite at depth) where greatest accuracy was required. L. H. BRIGGS, D. A. PEAK and J. L. D. WOOLLOXAIL: Constitution of matairesinol. The constitution of matairesinol, $C_{20}H_{22}O_6$, melting-point 119°, from *Podocarpus spicatus* has been determined, and it is now shown to be $\alpha\beta$-di-vanillyl-γ-butyrolactone.

VIENNA

Academy of Sciences, June 6. STEFAN MEYER: Calculation of the velocities of α-particles from their ranges, and its relation to the number of ion-pairs produced. FRIEDRICH KOCH and FRITZ RIEDER: Nuclear γ-radiation of beryllium. Investigation of the γ-radiation from α-irradiated beryllium by means of a Wilson chamber in a magnetic field shows that, in the formation of electron-twins, equal distribution of the available energy occurs. The numerical distribution of positrons and photo-electrons for different energies indicates the existence of several γ-lines. WALTER KOSMATH and OTTO GERKE: The radioactive climate and conditions of Badgestein, its bio-climatic and balneological significance. KASIMIR GRAFF: (1) Observations on the brightness, and (2) measurements of the colour, of Nova (1934) Herculis from December 1934 to April 1935. (3) Visual visibility of the Pleiades nebula and of nebula *NGC* 2237. (4) The diffuse nebulæ in the region of Orion. ERICH HAYEK: Formation of mixed crystals with tin monoxide. Mixed crystals of tin monoxide with oxides of other divalent metals—even with those stable as hydroxides under the experimental conditions—are obtained by precipitation from the appropriate salt solutions. The crystals show characteristic colours and their individuality is confirmed by their X-ray diagrams. MAX TOPERCZER: Daily variation of atmospheric dullness at Innsbruck. LEOPOLD VIETORIS: Groups of polydimensional paths. LEOPOLD KOBER: Geological investigations in the Apennines, especially of Calabria. KARL FEDERHOFER: Influence of the axial extension, inertia of rotation and thrust on the frequency of the bending of a circular ring. HUGO RÖSSNER:

Birds collected during the Austrian expedition to Asia Minor in 1934. R. EBNER: Gryllides and tettigoniides from the Anglo-Egyptian Sudan. About twenty species are enumerated and two new species, *Gryllus chopardi* n.sp. and *G. depressiceps* n.sp., are described.

Mechanism of Society

THE limitations which are being placed on scientific work in certain countries have forced many scientific workers, otherwise indisposed to concern themselves with political affairs, to realise that science and politics cannot be kept entirely apart. The direction of scientific investigation is in fact determined by social conditions to a much greater extent than is commonly realised by the scientific worker, and it is probably true that technological development rather grows out of than determines social needs. While science has undoubtedly been unjustly blamed for many of the evils which have resulted from the application of scientific discoveries, the danger of a reaction against science is sufficiently real to make it imperative for the scientific worker to pay much more attention to the social and political consequences of his work.

The limitations to which we refer, however, go far beyond this, and constitute a threat to the quality of scientific work as well as to its quantity or direction. They raise fundamental issues which cannot be evaded, and they could scarcely be more lucidly and forcefully put than in Lord Davies's book entitled "Force", which has recently been made available in a cheaper form*. This is essentially a scientific study of the right or moral use of force in every sphere of human society, and especially in international relationships.

While few in the world of science do not now realise the impracticability, if not the impossibility, of drawing a distinction between pure and applied science, there are still many who fail to realise that science on the scale it is pursued to-day is an integral part of the social organisation of the State. Wherever he works, the man of science is a part of the machinery of State, and there is no real immunity of science from its political environment. If the scientific worker desires liberal endowment for his work and reasonable freedom in its direction, he must at least make an effort to secure the understanding and support of those responsible for the government of the State in which he serves.

In some countries to-day, that sympathy and support can only be secured at the price of the acceptance of particular political dogmas and views which are in the lineage of those credulities and superstitions from which in the past science has liberated the human soul. It is not merely the quantity and direction of scientific work that are involved. Reason is again being pitted against passion and prejudice, and the shackles which we once thought science had finally shattered are in danger of being riveted again, perhaps even more firmly, on the minds of men.

Under such conditions, the quality of scientific work cannot long remain untainted, and this reason alone should quicken the interest of the scientific worker in Lord Davies's theme. Moreover, when many, both within the ranks of science and without, are coming to consider the ways and means by which the work of government can be more and more based on a scientific study of the available facts, and less and less upon mere prejudice or guess-work, we are witnessing in one country after another the sweeping away of individual rights, systems of justice and hard-won political liberties.

In such circumstances, it is imperative to

* Force. By Lord Davies. Re-issue. Pp. x+242. (London: Constable and Co., Ltd., 1935.) 3*s*. 6*d*. net.

discover the fundamental causes of these failures whether in the national or international sphere. Lord Davies finds it simply in the failure to recognise and act upon the fundamental principle that the exercise of force should be limited to the police function. Force is either the servant of justice or the tool of policy, and in a series of lucid and forceful chapters he shows how failure to recognise this principle is the root cause of the loss of liberty and the growth of political oppression and tyranny in Europe to-day, as well as of the failure of the League of Nations to develop into an international authority with the power to ensure justice and peace.

Examples are quoted from recent history in a masterly manner in support of this thesis, including some trenchant criticism of the Irish policy of successive British Governments, but always Lord Davies is honestly endeavouring to face the facts in post-War Europe and to supply a moral basis for dealing with the most urgent problems of to-day. Inevitably he comes once more to his well-known view that force can only be rightly employed in the international sphere when it has been scientifically organised as the sanction of international law in the form of an international police force.

The issues with which we are faced in this way are urgent. Without dwelling unduly on the horrors of modern warfare, Lord Davies reminds us of our fatal habit of thinking of the next war in terms of the last and failing to face the facts of a scientific age. We cannot take all the powers and advantages with which science has now endowed us without in certain directions accepting restrictions upon our freedom of action, whether in such a matter as the use of the highways or in this matter of the use of force. The measures now being taken by the Air Raid Precautions Department of the Home Office will delude no reasonable person into thinking that any effective defence against air attack is possible, short of the abolition of war.

Lord Davies maintains that the only defence against a potential aggressor is to implant in his mind the certainty of an overwhelming reprisal by a superior force, under the control of an international executive and backed by the moral support of an impartial authority such as the League of Nations. The weakness of the collective system without such an international police force ready for instant action against an aggressor is apparent, and no thinking man can be blind to the narrowness of the verge between the downfall of the collective system and international anarchy and disaster. This is a matter which concerns the scientific worker and every other citizen of good will. The vast increase in the potentialities of force during the last twenty-five years through the application of scientific discovery and invention indeed lay special responsibility on the man of science to assist in working out a solution.

If the primary task is one of education, scientific workers have definite responsibilities in that work. They must lend all their energy to the creation of a new mentality as favourable to the constructive use of force in national and international affairs as the old outlook on war has been hitherto in destruction. The peaceful evolution of institutions, whether on a national or an international scale, depends for its realisation upon the ability of men to agree upon the purposes they must have in view. The whole process of politics depends upon the assumption that reasoned discussion will secure effective agreement about whatever elements of justice are to be found in any proposed arrangement, such as an international police force; and in securing such agreement scientific workers must play a part neither more nor less than that of other sections of the community.

In the present structure of society, the participation of the technician and scientific worker, as of the administrator and professional worker, is indispensable, if that inherent tendency of institutions, which have once rendered invaluable service but are now archaic and declining, to delay the evolution of new and more appropriate institutions, is to be overcome by constitutional means. Adaptation is the secret of existence; and it is only as we accept the challenge thrown down by these issues and seek to develop by clear and courageous thinking and bold experiment that society can avoid self-destruction, and turn its new powers into instruments of security. Creative and adventurous thinking as well as a scientific approach are demanded, and scientific workers must recognise their responsibilities and utilise to the full those opportunities of creative work which lie before them in this field. In this way the dark menace which now overshadows the world may be dispelled, the limitations on human thought removed and science regain its full freedom of creative endeavour, while new fields of effort will be opened up in which the scientific method and spirit may win yet greater triumphs for the human race in its mastery of its environment.

The Beginnings of Applied Chemistry

Origins and Development of Applied Chemistry
By Prof. J. R. Partington. Pp. xii+597. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1935.) 45*s*. net.

THE evolution of an idea or event usually makes a very interesting story, and probably none more so than the origins of some of the industrial applications of chemistry. Indeed, several of the modern chemical arts have been practised for thousands of years in forms which become more and more primitive and obscure as they are traced backwards, until at last their humble origins are lost in the haze of prehistoric antiquity.

Many charming stories have been written about one or other of those chemical industries the origin of which antedates all books and writings; although, in some cases, industries have passed through many strange vicissitudes in their development, and have been ultimately abandoned, for, as Lucretius has said:

> The rolling years bring on a change of things;
> What once was valued loses all worth,
> And what was worthless rises in its stead.

In the work under notice, Prof. Partington has presented a wonderful and valuable account of the sources, production and uses of materials in Egypt, Babylonia, Assyria, the Ægean, Asia Minor, Persia, Syria and Palestine, from the earliest times to the end of the Bronze Age—"wonderful" because of the painstaking care in handling so large a mass of evidence involving, we are informed in the preface, 7,000 references; and "valuable" because it supplements so effectively and pleasantly our general knowledge on the historical side of industrial chemistry.

Each territory is treated as one unit, so that the origin, occurrence, manufacture and use of a given material, say, iron, are described country by country. Some might consider that it would have been better to have collated the data with reference to each material, as E. O. von Lippmann did towards the end of his "Entstehung und Ausbreitung der Alchemie" (Berlin, 1919–31). I think that Prof. Partington has adopted the better plan; the alternative would probably have been preferable had the narratives extended through the Middle Ages.

The materials treated in Prof. Partington's book include the metals and alloys: copper, silver, gold, zinc, brass, mercury, tin, bronze, lead, arsenic, antimony, iron and steel, cobalt, nickel, and platinum; and various chemical compounds—common salt, natron, sal ammoniac, nitre, alum and vinegar—as well as sulphur; the gem-stones—natural and artificial; building materials—plaster, stucco and bricks; pigments and paints; ink for writing; oils—expressed and distilled; pomades and ointments; incense and perfumes; products derived from plants; medicinal preparations; and fermented drinks and other beverages. There is a temptation to select one or two items in the list to illustrate in detail how thoroughly the work has been done, and to compare that work with evidence collated in other ways.

Operations connected with the arts of metallurgy, dyeing, weaving textiles, tanning leather, brewing, baking, embalming, pottery, glass-making and the imitation of gem-stones, are also described. Here we can see the beginnings of many an industry practised in modern times; and that not always to the credit of the later workers, judging by what they have accomplished with their heritage—*St. Matthew* xxv, 25.

The data confirm M. Berthelot's belief that chemistry is founded on knowledge slowly accumulated by practical discoveries in metallurgy, medicine and other arts; and the opinion of J. B. A. Dumas when he said:

> Let us confess at once, without going round the subject, that practical chemistry took its rise in the workshops of the smith, the potter, the glass-blower, and in the shops of the perfumer.

Of course, the mere mechanical practice of operations, essentially chemical in their nature, does not make the early artisans into chemists in anything but name. Otherwise, the first man to light a fire, stew a rabbit, or roast a pig might have been styled the father of chemistry. In the words of A. F. de Fourcroy (1782):

> It is vain and ridiculous to attempt to trace the origin of chemistry to the first men who worked in the metals, cut and polished stones, fluxed sand, or dissolved and crystallized the salts. This would be analogous to an attempt to trace the elements of geometry in the efforts of the savage to trim irregular fragments of rock to a more regular form in order to adapt them to his first needs.

The index is worthy of the book; it is singularly complete, occupying as it does 65 pages, three columns per page. It is difficult to see how those interested in the subject can carry on economically without the assistance of the "Origins and Development of Applied Chemistry".

J. W. MELLOR.

Gymnosperms

Gymnosperms: Structure and Evolution
By Dr. Charles Joseph Chamberlain. Pp. xi+484. (Chicago: University of Chicago Press; London: Cambridge University Press, 1935.) 21*s*. net.

EVEN in these days of specialisation, no real botanist dismisses the Gymnosperms from his field of study. They still possess an inherent interest, although for a hundred years they have been classic ground. The first impulse came from Robert Brown, who first realised the morphological significance of the Gymnosperms. From that beginning the knowledge of them has been built up by generations of botanists, from Hofmeister, to D. H. Scott in our own day. The attraction of the group depends on the strategical position which they occupy in relation to Angiosperms and Pteridophytes, respectively. This morphological and evolutionary ascendency really derives from the fact that Gymnosperms abut on a rich hinterland of fossil petrifactions so well preserved that their investigation has given, and should continue to give, convincing results. All this is fully appreciated by Prof. Chamberlain, and forms indeed the *raison d'être* of the present book.

American botanists have taken an important share in the advancement of Gymnosperm knowledge, owing to (1) the large numbers of living conifers which grow in the forests of the North American continent, the life-histories of which have been worked out, especially by the school of Coulter and Chamberlain at Chicago; (2) the richness of the country in Bennettitales as elucidated by Wieland; and (3) the intimate studies of living Cycads by Prof. Chamberlain himself, who in his world-wide travels has seen, studied and collected, in its own habitat, every genus and a large number of species of existing Cycads. This contact with his material in the field is an admirable and outstanding feature of his book. In this connexion, frequent reference is made to the question whether Gymnosperms are ever effectively pollinated by insects. The matter is one of importance as on its determination must rest any decision as to whether evolution at the Gymnosperm stage has been influenced by insects, as it undoubtedly has been in the more modern Angiosperms. Prof. Chamberlain is sceptical as to existing evidence: "In spite of occasional claims, it is very doubtful whether there is a single case of insect pollination in any Gymnosperm".

All the same, it is an attractive and important field for properly directed and methodical investigation, because much depends upon it. In some Palæozoic seeds, for example, *Physostoma*, as many as four hundred pollen grains have been counted in the pollen chamber, and it is difficult, unless a very prolonged exposure of the micropyle be presumed, to account for such bountiful supplies on the hypothesis of wind carriage alone.

The book has a definite style of its own which may be best compared to the 'running commentary' of the broadcaster. Otherwise stated, a previous knowledge of the subject matter is required for benefit to be derived. To say this is not to condemn the book (which indeed is brightly written) though it does cast some doubt on its utility for the purposes of undergraduate students (cf., dust cover). The comparative morphology, anatomy and embryology of the various living groups of Gymnosperms are well displayed, though too many dogmatic statements have crept into the text. The illustrations are excellent and many previously unpublished. If anything, they are too generously provided, and a few of the redundancies might be usefully replaced by distribution charts.

It is natural that the book should (apart from the non-Cycadian fossils) be based largely on American researches, as these have been a great feature in the output of the Department of Botany at Chicago, as developed by the late Prof. J. M. Coulter and his colleague, Prof. Chamberlain. For the fossil data (other than Bennettitales) the results of European work have been incorporated, and indeed form the evolutionary foundation of the book. Lack of practice in palæobotanical technique is responsible for a few fantastic statements, but they are not real blemishes. Though America has not yet made available the relevant petrifactions that would have made this book 100 per cent American, the author gets his revenge by taking his readers for a personally conducted tour through the beautifully arranged and reconstructed carboniferous forests of the Field Museum at Chicago! Nothing approaching these exists in Europe.

Prof. Chamberlain reproaches his "English friends" for their persistent use of the name Pteridosperms for seed-bearing plants having the habit of ferns—and employs the term Cycado-filices. Reference to the original source (No. 431 in the Bibliography), where this group was established, would disclose the grounds for so doing, together with the reason why "Cycado-filices"

seemed inadequate. This latter name had been proposed by Potonie to cover the whole series of vegetative remains showing structural relations with both Ferns and Cycads. The term Pteridosperm is reserved for the elect among these—to be included if and when they are proved to have possessed seeds. The unassigned residue (which may remain in the convenient 'waste-paper basket' of Cycado-filices) should include both unverified Pteridosperms and perhaps other plants which never attained to the status of seed-bearing.

X-Rays in Pure and Applied Science

(1) Handbuch der Physik

Herausgegeben von H. Geiger und Karl Scheel. Zweite Auflage. Band 23, Teil 2: Röntgenstrahlung; Ausschliesslich Röntgenoptik. Redigiert von H. Geiger. Pp. ix+541. (Berlin: Julius Springer, 1933.) 56.70 gold marks.

(2) Industrial Radiography

By Dr. Ancel St. John and Herbert R. Isenburger. Pp. ix+232. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1934.) 21*s.* 6*d.* net.

(3) Les rayons X: au laboratoire, à l'hôpital, à l'usine

Par Marc Privault. (Actualités scientifiques et industrielles.) Pp. 204. (Paris: J.-B. Baillière et fils, 1934.) 25 francs.

THESE three books, very different in type and in object, serve to illustrate the intensely specialised nature of modern physics, and also the high degree of specialisation within its fairly clearly defined sub-branches.

(1) The second edition of vol. 23 of the well-known "Handbuch der Physik", edited by Geiger and Scheel, treats of several branches of radiology from the academic point of view. The confines of one volume have proved inadequate for the revision of a subject growing so rapidly, and vol. 23 now appears in two parts. In part 2, Profs. Bothe and Kirchner deal with the absorption and scattering of X-rays, Dr. Kulenkampff writes on the continuous X-ray spectrum, Prof. Ewald discusses the study of the solid state by means of X-rays, and Dr. Steinke contributes a section dealing with cosmic rays.

The contributions of Bothe and Kirchner and of Kulenkampff are considerably longer than those of the first edition, and bring the topics up to date. The section by Ewald, which is new, opens with a clear and detailed account of crystal classification and space-grouping, deals adequately with X-ray interference, temperature and atomic effects, and the design and use of X-ray spectrometers. A very valuable chapter deals with the interpretation of powder photographs and the usual projections used in this work. The rapid advance of the study of cosmic radiation is shown by the fact that, although the subject has only been seriously investigated for some seven years, the physical nature and properties of the radiation are now fairly well known. Much, however, remains to be done before we have a clear understanding of the origin of the cosmic rays. That they originate in space appears to be beyond doubt, but whether their occurrence is due to atomic disintegrations in young stars or spiral nebulæ, whether they arise through some interaction of interstellar matter with electrified particles (or perhaps neutrons), or whether their genesis is due to some physical phenomenon at present outside our knowledge is one of the problems which is yet to be solved. The experimental side of the work is set down in considerable detail by Dr. Steinke, together with a brief but adequate summary of the somewhat speculative theories of the origin of cosmic rays.

One cannot praise this volume more highly than by stating that it maintains to the full the high standard set by the other and well-known volumes of the "Handbuch der Physik".

(2) "Industrial Radiography" by St. John and Isenburger is a treatise for the technician, and within the limits of its title is self-contained and complete. The first seventy pages contain an account of the general properties of X-rays and the construction of X-ray apparatus which will probably be found adequate for a proper understanding of the later parts of the book. The importance of a proper photographic technique and accurate dark room manipulation of films is rightly stressed. One frequently finds operators taking great pains in adjusting objects to be radiographed, making exposures with carefully controlled voltages and exposure times, and then developing and fixing in stale solutions at unsuitable temperatures, apparently unaware that such processing conditions give radiographs in many respects similar to those which would result from using quite different kilovoltages and exposure times. The importance of using dark rooms of

ample size and provided with good ventilation is also emphasised.

Industrial radiography is largely concerned with making radiographs of metal objects, often with thick walls and of irregular shape, and the correct setting up of such objects frequently presents difficulties. The authors have apparently had a very wide experience of this work, and have included in the book a large number of practical points which are likely to be of great service to those whose experience is more limited. Similarly, the radiography of small objects has its own peculiar problems, which again are dealt with adequately.

A chapter is devoted to radiography with radium gamma rays (the authors call the resulting pictures 'gammagraphs' to distinguish them from X-ray pictures which they call 'exographs'), a method of attack which seems likely to increase in use, particularly since the influence of scattering on the radiographs is much less with gamma rays than with X-rays, and therefore much thicker objects may be successfully examined.

The book is characterised by a large number of illustrations carefully chosen to show how common defects in metals appear on radiographs. In very many cases the radiograph appears by the side of a photograph showing the defect, and not infrequently photomicrographs are also given.

An appendix contains a valuable set of exposure charts showing the exposures required at various voltages for various thicknesses of aluminium, steel and copper, a chart from which the exposure required for gamma ray radiography of steel objects may be found and also a very complete bibliography.

The authors are to be congratulated on producing a practical treatise which should be invaluable to novices and a useful reference work for all industrial radiologists.

(3) "Les rayons X" by Privault is an introductory textbook, touching on all the principal aspects of X-rays from the points of view of both pure and applied science. With so comprehensive a field, it must follow that the treatment of each branch of the subject is somewhat meagre. One feels that it is impossible to give even a reasonably adequate summary of the present state of all the branches of radiology (using the word in its widest sense) within the limits of two hundred small pages.

The Profession of Librarian

Rôle et formation du bibliothécaire: étude comparative sur la formation professionnelle du bibliothécaire. (Dossiers de la Coopération intellectuelle.) Pp. 385. (Paris: Institut international de la Coopération intellectuelle, 1935.) 50 francs.

THIS volume is based on a questionnaire sent out by the International Institute of Intellectual Co-operation, and it provides the most detailed account of the status of librarians in various countries which has yet been published. Thirty-five countries or States are included in the survey, of which twenty-seven are in Europe, the others being South Africa, Brazil, Canada, China, the United States, India, Japan and New Zealand. The information asked for by the questionnaire related to the categories of librarians and libraries existing in the country concerned, the authorities to which they were subject, the qualifications required of candidates for the library profession, whether and what diplomas or other examinations were available and the particular courses of study provided in connexion with them, and their location and control.

The work should prove of the greatest value to all interested in the library profession and the improvement of librarianship as a whole. It is very desirable that the volume should have a wide circulation so that the people of all countries may realise that the average librarian is required to know a great deal more than how to hand books out to a reader. It is gratifying to note the progress that has been made in recent years, and especially since the War, in many countries to ensure that librarians shall be men and women of high educational standing and that their emoluments shall be reasonably adequate. In the Netherlands, for example, every public library official is expected to hold a special diploma, and any Government subvention is withheld from a library the personnel of which is wholly or in part without a diploma.

The chapter on England is written by Mr. J. D. Cowley, director of the School of Librarianship of the University of London, and is an admirable summary of the organisation of libraries and the facilities for the training of librarians now available. It is interesting to note that candidates for a librarianship in Brazil have to produce, among other things, a certificate of good manners, as well as one of good health. Even in China, since 1927,

intending librarians have to pursue a course of study in a school of librarianship in China or elsewhere, possess a diploma of a university or college and also practical experience of more than one year, while junior assistants must possess a certificate of secondary education.

Possibly the most extensive course is that in Russia, where no fewer than twenty-four colleges of library economy have been founded. Admission to a college is granted to persons who have terminated a secondary school course of seven years, and the plan of study in the library college extends over three years, a total of 4,426 hours being allocated to the different subjects, which include physics, chemistry, mathematics and graphic processes, in addition to the strictly professional topics. Of special interest is the fact that, of the 1,440 hours of study allocated to the third year's studies, 82 have to be devoted to Leninism.
